first, whether the feast was to be a version of the Passover, to be kept on the fourteenth day of the moon, or an anniversary of the Resurrection, to be kept on the first day of the week; secondly, in what manner the full moon was to be predicted. The details of this dispute do not affect us here, except in one point. It seems clear that towards the end of the 2nd century, the Metonic cycle of nineteen years was frequently introduced into the reckoning. It is the peculiarity of this cycle of nineteen years [Periods of Revolution], that the new and full moons return to the same days of the month, generally speaking; that if, for instance, a full moon fall on the 10th of March in any year, it is most likely to fall on the same day in nineteen years, and certainly on the 9th or 11th, if not on the 10th. The astronomers, and all who predicted celestial phenomena for common use, used this Metonic cycle; several modern writers on ecclesiastical history speak as if the Christians had invented the cycle of the golden number, which is only the Metonic cycle with its commencement altered. But it is material to notice that all countries unto which Greek civilisation had found its way, had their new and full moons predicted by this cycle.

The Nicene Council (A.D. 325) attempted to bring about a general usage in keeping Easter. What is left of this council is its creed, a synodical epistle, and twenty canons. Whether those canons which now exist be the genuine work of the Nicene Council is nothing to our present purpose, for they do not mention Easter at all; nor should we have noticed them here, had we not seen them cited by name in reference to Easter, to give, as it were, an impression that the council had laid down rules on the subject in a definite form. All their interference in the matter, as far as it can be collected from the earliest historians of the council, Socrates and Theodoret, is contained in one sentence of the synodical epistle, as follows:—"We also send you the good news concerning the unanimous consent of all in reference to the celebration of the most solemn feast of Easter, for this difference also has been made up by the assistance of your prayers; so that all the brethren in the East, who formerly celebrated this festival at the same time as the Jews, will in future conform to the Romans and to us, and to all who have of old observed our manner of celebrating Easter." The case is clear enough: there was a great schism between the Easterns and Westerns,—not an astronomical schism, but a part of the great conflict between the Jewish and Gentile Christians; and the council simply decreed that the former should adopt the usual practice of the latter. St. Ambrose, in the next generation, in a letter written A.D. 386, says that the council had got up the method of the cycle of nineteen years, which they had named *Enneadecaëteris*; that is, Ambrose was not astronomer enough to know that both the thing and the name had been current even in elementary works for hundreds of years before the council. In this, as we have mentioned, he has had followers; indeed, the necessity of accounting for the cycle of nineteen years in some way, and the want of knowledge of its astronomical history, has in a manner compelled theological writers to lay it at the door of the Nicene bishops, and thence to infer that they paid a very particular attention to the astronomical part of the settlement of Easter. But in fact their object was merely to keep the Eastern Christians from celebrating the Jewish Passover. So long as this point was gained, they do not seem to have thought it necessary to interfere, even as regarded the East, with those differences of astronomical method, which they do not even mention, though they could not be ignorant that they existed in the West. And the result was as follows: from the time of the Nicene Council little or nothing more is heard about celebrating Easter on the 14th, instead of the Sunday after, while the disputes about the astronomical cycle of Easter recommenced almost immediately, and lasted for centuries.

Eusebius of Cæsarea, the historian, informs us in his life of Constantine that he had presented to that emperor a treatise on Easter, wherein the mystic character of that festival was explained; apparently a purely theological work. Jerome ('de Scriptor. Eccles.') mends this statement, and informs us that Eusebius was the author of the cycle of nineteen years. Bede and others have copied Jerome, and Clavius (see the article cited at the beginning) brings forward Bede as more clearly explaining a statement of Ambrose to the same effect. Now Ambrose mentions no such thing; and meeting with the statement of Jerome since we wrote that article, we are inclined to suppose that Clavius meant to have quoted one of the contemporary saints, and wrote down a citation from the other,—a supposition which would explain what must otherwise be called a disingenuous proceeding. Hence comes the current story that Eusebius and others were appointed by the council a committee to superintend the drawing up of the rule.

Shortly after the Nicene Council there were disputes about the proper cycle for Easter. It is unnecessary here to note the various cycles which were proposed. It was not till the time of Pope Hilarius (A.D. 463) that the cycle of nineteen years obtained a permanent footing. The pontiff employed Victorinus of Aquitaine to correct the calendar; and Victorinus actually constructed the cycle of 532 years, or of 28 Metonic cycles. When Dionysius Exiguus (A.D. 530) altered the mode of reckoning, and abandoned the Diocletian era in favour of what he supposed to be the year of the birth of Christ, he adjusted the mode of reckoning employed by Victorinus accordingly, and the cycle of the latter has ever since been called Dionysian. From his time till that of the Gregorian reformation the rule was strictly observed, no disapprobation producing anything but written arguments. So that the Nicene Council neither succeeded, nor, we assert, intended to succeed, in doing more than destroying, among the great bulk of Christians, what was called the *quartadeciman* heresy, the opinion that Easter was to be kept on the fourteenth day of the moon,—the opinion, in fact, that Easter was *the Passover*. The settlement of the arithmetical or astronomical question is the work of Hilarius and Victorinus. Not but that these reformers considered themselves as fulfilling the intentions of the Nicene Council: in fact, all parties after the council made it their authority. All dissentients assumed theirs to be the Nicene faith in this matter; and even the blunder of the British Parliament has been defended by supposing it to be the true intent of the assembled bishops in the 4th century.

The assumption of the so-called Dionysian cycle involved two errors. The Julian year being too long by about a day in 130 years, threw the vernal equinox back by a day in that time; while the rule of the cycle supposed that the equinox remained fixed on the 21st of March. Again, the cycle of nineteen years, which supposes 235 lunations to fill up that time exactly, was wrong in a manner which caused the new moons of the calendar to advance a day in every 300 years. The consequence was, that by the time of Pope Gregory XIII., in 1582, the equinox had receded to the 11th of March, while the calendar new moon generally fell on the fourth day following that of the real new moon. These errors were obvious enough to every astronomer. Sacrobosco and Roger Bacon pointed them out in the 13th century. The former says they must be borne on the authority of the council; the latter strongly recommended Pope Clement to make an amendment, and gave a reformed plan which is perfectly good. He had (and where he got it from we cannot guess) the length of the year more correctly than any of his predecessors or contemporaries. Cardinal Cusa and Regiomontanus, in the 15th century, pointed out the necessity of a change. Stöffler, Pitatus (who proposed the plan afterwards adopted with the leap years), Paulus Forosemproniensis (bishop of Fossombrone), and others in the 16th century, wrote in advocacy of the same thing. The Council of Trent sanctioned an alteration, and referred the details to the see of Rome. A plan was presented to the pope by the relatives of one Aloysius Lilius, deceased, who had occupied himself with the subject. This plan was approved of; and in 1577 a circular was forwarded to princes and universities throughout the Catholic world, stating the nature of the intended alterations, and inviting suggestions. The Jesuit Clavius was the person, or the principal person, to whom the concoction of the scheme was intrusted. March 1, 1582, a bull was published, dated February 24th, 1581, abolishing the old calendar, giving a general description of the new one, and announcing that it would be fully explained in a forthcoming work. Clavius published this work, namely, 'Kalendarium Gregorianum Perpetuum,' 4to, Rome, 1582 (pp. 60); and it was reprinted in the folio collection of his works. We have nothing here to do with the alteration of the style, but only with what relates to Easter. This calendar had to undergo several severe attacks, particularly from Joseph Scaliger, Moestlinus, and Vieta [Vieta, in Biog. Div.]; but these, of course, produced no effect against established authority, nor, in truth, ought they to have done so in this instance. The calendar answers its purpose exceedingly well, and is, astronomically speaking, better than it was supposed to be by Clavius himself.

Referring for a full description of the details to the article in the 'Companion to the Almanac,' we shall give a slighter account of the process. Clavius held astronomical considerations to be secondary in importance to the general notions of his predecessors and contemporaries. One of these was, that it was not desirable ever to keep Easter on the same day as the Jews keep the Passover. To avoid this, he uniformly lessens the moon's age by a day, taking care, as much as possible, that all the necessary errors of the imperfect cycle shall have the same effect, namely, that of lessening the moon's age, or throwing the new moons forward. Accordingly, his new moons are seldom on the real day, generally one or two days in advance, about as much of one as of the other, and sometimes even three days in advance. It is therefore very important to remember that the moon of the calendar is not the moon of the heavens, and not even the mean moon of the astronomers. So that in the act of parliament, instead of the full moon (being the fifteenth or sixteenth day) of the heavens (the first day being that of new moon), should have been read the fourteenth day of the moon of the calendar. There is evidently a compensating effect; the fourteenth day of a moon, which begins for the most part one or two days after the moon of the heavens, is of course generally the fifteenth or sixteenth day of the moon of the heavens.

Clavius uses the Dionysian cycle in a way which we may describe as follows:—Neglecting the preceding arbitrary alteration, which may be made once for all when everything else is done, there are two things to be provided for. First, the defect of the cycle itself, the error of which is to advance the new and full moons by a day in about 300 years; Clavius took it to be eight days in 2500 years, and accordingly he allowed one day for seven periods of 300 years, and then one day for a period of 400 years, as we shall presently see. Next, the abandonment of three leap-years in every four centuries, which, though necessary for keeping the equinox at or about one day of one month, would destroy the efficiency of the cycle of nineteen years. There are then two shiftings, as it were, of the cycle necessary—arbitrary alterations of the moon's age at certain periods (we are now speaking only of the calendar moon). We shall now give a set of cycles, resembling the one already given, which is that of our own time, from which we shall be able to make the shifts apparent, and to connect them with the above-mentioned necessary corrections. Tables of this form were not given by Clavius himself, but were published in England, we believe by Lord Macclesfield, at the time of the discussions preceding the alteration of the style in 1752.

In the first column are the days of the month, from March 21 to April 25, and Easter may fall on any one of these days except the first. In the second column are the dominical letters, explained in DOMINICAL LETTER, and which can be found by the table there given. In leap-year, take the second letter of the year in finding Easter. Then follow certain columns, each of which has a heading to show to what years it belongs. Thus, the column headed 1700–1899 belongs to all years from 1700 to 1899, both inclusive. These columns contain the nineteen golden numbers variously dispersed. Every year has its golden number found thus: add 1 to the year and divide by 19; the remainder, or 19, if there be no remainder, is the golden number.

Take the first of these columns, namely, 1583–1699. Opposite to April 8 is written the number 15. This means that, from 1583 to 1699, whenever the golden number is 15, the fourteenth day of the calendar moon is the 8th of April. And so in like manner throughout these columns each golden number is written opposite the day which is the fourteenth of the calendar moon when that golden number occurs. Thus from 2600 to 2899, the fourteenth of the paschal (calendar) moon is always on the 2nd of April whenever the golden number is 16.

Let us now suppose the first column constructed. It is contrived, as before noticed, so as to make the calendar full moons follow the real ones. To keep this up, whatever alterations must be made in a cycle adapted to the real moon, the same must be made for the calendar moon. As far as 1699 no alteration is requisite, for Clavius does not make the first alteration on account of the incorrectness of the cycle till 1800, and the year 1600 is leap-year in the Gregorian calendar as well as in the old one. The reader must remember that the cycle of 19 years is one in which every fourth year is leap-year. As soon as 1700 comes, we have a fourth year which is not leap-year, so that the day which would have been called February 29 is called March 1, and so on. Each golden number then is written one place lower from 1700 to 1899; though it would better have represented the reason of the change if each day of the month had been written one place higher. The same thing takes place at 1800; but here Clavius puts the moon back a day, or makes his calendar moon a day older, to correct the accumulated error of the cycle. But the previous step makes the calendar moon, at any given day, a nominal day younger than it would otherwise have been. These two changes destroy each other's effect in 1800, and the cycle continues unaltered till 1899. At 1900 the first change is repeated; but 2000 *is* leap-year in the new calendar, and therefore no change is then requisite. And again, though 2100 is not leap-year, yet as 300 years have elapsed, the correction for the fault of the cycle is introduced at the same time with that for the abandoned leap-year, and the two destroy each other's effects, as before. This column then is good till 2199. The next column is now easily explained: but in the next one to that, or 2400–2499, we begin with a year in which the correction for the cycle is to be made without being destroyed by that arising from abandoning leap-year. That is, the moon, on any given day, is to be a day older than it would otherwise have been. The numbers must then each be put back a day, which is seen to be done. In this manner, if it be remembered that, beginning at 1800, seven following corrections of the cycle are made at the end of periods of 300 years each, and then one at the end of 400 years—the reader would be able to construct farther cycles for himself, if it were not for one peculiarity which we now notice.

At the bottom of the columns it will be seen that there are in one or two places numbers which do not rise or fall with the rest. This was a sacrifice of uniformity to the desire of preserving one characteristic of the old calendar, namely, that the fourteenth of the calendar moon never fell on the same day of the same month at any two epochs which were within nineteen years of each other. This would have happened sometimes, owing to the corrections above described: and Clavius took a very simple method of avoiding it, which is explained in the article already cited. The effect of his method is to produce the slight departure from uniformity of alteration above noted.

It will thus be seen that in the calendar which is now in use, one, two, or even three days of error have not (provided the moon was made too young, not too old) been thought of so much consequence as either ease of calculation, or attention to existing notions upon the subject. Of this we entirely approve, and agree with Clavius in asserting that any rule which is fixed would be better than diversity of usage.

To find Easter by the preceding table, first find the golden number, and then the dominical letter. [DOMINICAL LETTER.] Take the proper column, and find out the day opposite to which the golden number stands. Go on from that day to the next *following* day which has the dominical letter opposite to it: that day is Easter Sunday. For example, take 1847. Add one, and divide by 19; the remainder is 5, the golden number. The dominical letter found in the article cited is C. In the column 1700–1899, we find 5 opposite to March 30, which is the fourteenth of the calendar moon. The next C is opposite April 4, which is Easter Sunday.

Again, to find Easter in 2384. Divide 2385 by 19, and the remainder is 10, the golden number. The dominical letter (the second) is G. In the column 2300-2399 the 10 is opposite to April 7, and the next G is opposite to April 8, which is Easter Sunday.

The dominical letter may be found by a short calculation as follows:—

I. Add one to the given year.

II. Take the quotient of the given year, divided by four, neglecting the remainder.

III. Take 16 from the centurial figures of the given year, if it can be done.

IV. Divide III. by 4, neglecting the remainder.

V. From the sum of I., II., and IV., subtract III.

VI. The remainder of V., after division by 7, is the number under dominical letter in

G	F	E	D	C	B	A
0	1	2	3	4	5	6

But if the year be leap-year, it is the second dominical letter which is thus found.

As instances, take 1847 and 2384, as above given.

I.	1848	2385
II.	461	596
III.	2	7
IV.	0	1
V.	2307	2975
VI.	4 (C)	0 (G)

The above is for new style; for old style proceed as follows: To the number of the year add its quotient when divided by 4, and 4: the remainder, after division by 7, is to be used as the VI. of the preceding rule. Thus for 1583, we have

1583
395
4

283 Rem. 1. Dominical Letter F

The cycle for Easter-day, old style, is given at the beginning.

The sole authority on the subject of the Gregorian Calendar is, of course, Clavius, the authorised contriver of it, or at least the person to whom the other delegates of the Roman see (if indeed any of them took any share in the execution of the plan) intrusted the explanation of it. In his work already mentioned, he has given all the results for every year from 1600 to 5000: he thinks his rule will be correct enough as far as 8000. On the mathematical part of the calendar full information will be found in Delambre's 'Histoire de l'Astronomie Moderne,' and Lalande's 'Astronomy.'

With regard to the faulty explanation in the act of parliament, we find that it was copied literally from the Book of Common Prayer. In this work it appeared for the first time in 1662, directly after the convocation which met at the Restoration of the monarchy had made the alterations mentioned in LITURGY. The explanation was therefore added by this convocation. Supposing the calendar moon to be spoken of, it would have been correct if the second clause had been omitted. For the calendar full moon is always the fifteenth day, and it is clear that "the Sunday after the fourteenth, or the next Sunday if the fourteenth fall on Sunday," is the same thing as "the Sunday after the fifteenth, or the fifteenth itself, if it be Sunday." Finding definitions of Easter by the fifteenth, in the second of the two ways just mentioned, to have occurred in times anterior to the Restoration, we suppose that the explanation of 1662 was the result of a confusion of the two.

EASTER DUES. [OFFERINGS.]

EAVES. [HOUSES.]

EBB. [TIDES.]

EBIONITES, a sect of Christian Jews, which existed in Palestine and other parts of the East in the 1st and 2nd centuries of our era. Like the Nazarenes, with whom they have been often confounded, they continued to observe the precepts and ceremonies of the Mosaic law; they kept both the Sabbath and the Sunday, made their ablutions, used unleavened bread in the celebration of the Eucharist, and, moreover, abstained from eating flesh. Still they do not seem to have formed a distinct sect till after the second destruction of Jerusalem by Hadrian, when they became separated from the rest of the Church by their dogmas as well as by their external practices. Origen, Epiphanius, Eusebius, and other early fathers, distinguish two sorts of Ebionites,—namely, those who denied the divinity of Jesus Christ, asserting that he was the son of Joseph and Mary, though endowed with a prophetic gift; and those who maintained that he was born of a virgin, but denied his pre-existence as God. The Ebionites in general acknowledged only one gospel, namely, the Hebrew one, which goes by the name of St. Matthew, and that one mutilated. They discarded the Acts of the Apostles, and especially the Epistles of St. Paul, whom they considered as an apostate from the old law. They had several apocryphal books; among others, a life of St. Peter. The earlier Ebionites lived a regular life, and many of them observed celibacy, which they held in great esteem. The later Ebionites became much more lax in their morals. The name of Ebionites is said by Eusebius, Origen, and Irenæus, to be derived from a Hebrew word of contempt, meaning "poor low people," which the Jews applied to those of their countrymen who had embraced Christianity. Others have derived it from a philosopher of the name of Ebion, whose existence however is doubtful. Epiphanius speaks at length of the Ebionites, but he confounds them with other sects, and his account cannot be trusted. The Ebionites never rose into much importance, and exercised but little influence on the spread of Christianity. (Mosheim, *Institutes of Eccles. History*, with *notes* by Dr. Murdoch; Neander, *Kirchengeschichte.*)

EBULLITION (*ebullio*, to boil). Under BOILING OF LIQUIDS were given the chemical and physical aspects of ebullition. Under the present head we propose to notice what is called the *spheroidal state of liquids*, which has of late years attracted considerable attention.

In 1756 Leidenfrost called attention to the fact that, when water is allowed to fall upon a red-hot iron plate, it does not boil, but forms into drops, which roll or jump about for a considerable time. This experiment has attracted the attention at various times of such men as Klaproth, Count Rumford, Pouillet, and Dumas; and it came to be shown as a class experiment, in which case a small platinum crucible is strongly heated by means of a copious flame from the spirit-lamp, and water is dropped into it from a pipette: the water does not boil, but the drops coalesce and roll about with considerable activity. In this way about one-fourth or one-third of the crucible may be filled; and, provided the heat be well maintained, the water does not only not boil, but evaporates very slowly. If, however, the heat be withdrawn, the water remains quiet for about half a minute, and then suddenly bursts into steam and disappears. In 1837, Mr. Tomlinson ('Mechanics' Magazine,' No. 703) showed that other liquids might be substituted for water in the above experiment, such as pyroxilic spirit, spirits of wine, sulphuric ether, and even mercury; but the last is quickly dissipated. Such fluids as come into immediate contact with the hot metal, such as oil of turpentine, olive oil, and sulphuric acid, were immediately decomposed and failed to produce the effect. The same writer ('Students' Manual of Natural Philosophy,' 1838) also showed that many saline solutions could be used instead of water; but the most curious result obtained by him was the use of a hot liquid surface instead of a metallic one, such as a fixed oil, raised to the temperature of 450° or 500°. Some care is required in this experiment: the liquid, such as water, alcohol, or ether, must be delivered from a pipette, with a steady hand, directly on to the surface of the hot oil; not allowed to fall, otherwise the liquid may sink under the surface, generate steam with explosive violence, and scatter about the hot oil. If, while a globule of water be rotating on the hot oil, a globule of ether be also placed on it the two drops will coalesce and continue to rotate as one globule the ether forming the outer surface of the drop. Turpentine forms a disc on the hot oil, and quickly disappears by evaporation; but pyroxilic spirit and bisulphide of carbon form globules. Sulphuric ether also forms a globule on the surface of hot water and hot mercury. Sulphuric acid heated to about 400° may also be used as the heated surface for ether and alcohol; but turpentine and naphtha form discs which quickly blacken the acid. Mr. Tomlinson refers to an experiment by Perkins, in which a platinum capsule, pierced with a multitude of holes like a coffee-strainer, which would not of course hold water while cold, retained it when strongly heated in consequence of water assuming the spheroidal state.

The physicists who had examined this phenomenon were pretty well agreed that the water, when in the globular or spheroidal state, was below its boiling point. Of this there could, of course, be no doubt; but what the exact temperature was had not been determined, any more than why the liquids, in the midst of so high a temperature, should be so little influenced by it. Rumford supposed it to be due "to the reflection of caloric operating on the surface of the drops of water." Pouillet supposes that "the calorific rays emanating from the vessel traverse the water too easily when they are very hot." Dumas ('Chimie Appliquée aux Arts,' i. 32), while admitting the fact, thinks "it ought to caution us against the accidents which a steam-boiler is liable to produce, when raised accidentally to a high temperature; for it might happen that it ceases to furnish steam, and, nevertheless, a reduction of temperature would cause an explosion. Plates of fusible metal are especially useful in 'preventing accidents' of this kind, since they limit the temperature that can be attained by the boiler; for it is evident that a valve would not be raised at the moment when this singular phenomenon should display itself."

In 1845-6 M. Boutigny exhibited some remarkable experiments on this subject before the British Association, and in several institutions of the metropolis; among others, in the laboratory of King's College, where the writer had an opportunity of seeing them. The most remarkable effect was the freezing of water in a red- or white-hot crucible, for which purpose advantage was taken of the low boiling-point (that is, 140° Fahr.) of liquid sulphurous acid. This assumes the spheroidal state a little below 14°; and if water be dropped into the crucible, it immediately falls considerably below its freezing-point, and a lump of solid ice can be turned out of the glowing vessel into the hand. Faraday has even carried the matter further, by freezing mercury under similar circumstances, substituting for the sulphurous acid a solution of solid carbonic acid in ether. By means of this mixture, a degree of cold has been obtained equal to about —166°; and as mercury freezes at —39°, we can understand how the mixture will assume the spheroidal state in the red-hot crucible, and mercury be readily frozen. Boutigny also placed iodine on an ignited platinum capsule, when it melted, formed a spheroidal black-looking mass, which rolled about and gave off but little vapour. But when the source of heat was withdrawn, an abundant evolution of violet-coloured fumes took place. A thick cylinder of silver was heated to redness, and lowered by means of a wire into a glass of water, where it quietly remained for a considerable time. But perhaps the most remarkable result was the impunity with which M. Boutigny passed his hand backwards and forwards through a stream of cast iron as it issued from the furnace, thus showing that the old ordeal by fire was not so formidable a trial as would at first sight appear. The above phenomena admit of explanation: First, on the fact that, whenever the liquids are thrown upon strongly-heated surfaces, a portion of the liquid is immediately converted into vapour, upon which the globule rests as on a cushion. Now as this vapour is a bad conductor of heat, it shields the globule from the conducting powers of the heated surface. In the second place, the evaporation from the surface of the globule carries off the heat as fast as it arrives, and thus maintains the globule at a temperature below that of its boiling-point. The spheroidal form of the drop is a joint effect of gravity and cohesion among the fluid particles. There must also be taken into account the repulsive force exerted by heat under the circumstances. So necessary is the condition that the liquid in the spheroidal state shall be below boiling, that if a liquid actually in the state of ebullition be introduced into the red-hot crucible, its temperature sinks from 5° to 7° below its boiling-point.

According to Boutigny, all liquids are capable of assuming this state but in all cases the heated surface must bear a certain relation to the boiling point of the liquid: if the latter be low, the former must be comparatively low also. The required temperature depends partly on the conducting power of the plate, and partly on the latent heat of the vapour: as this is small, the heat of the plate may approximate more nearly to the boiling-point of the liquid. The lowest heat of the plate required to throw water into the spheroidal state is said to be 340° Fahr.; alcohol, 273°; ether, 142°. The temperature of each liquid in the spheroidal state is supposed to be as definite as its boiling-point. Boutigny gives 205·7° Fahr. as the temperature of the spheroidal state of water, 167·9° for that of alcohol, 93·6° for that of ether, and 13·1° for that of sulphurous acid. The spheroidal state may be produced in vacuo. In the experiment in which the moist hand is made to cut a stream of molten iron, the moisture of the hand forms the cushion of steam which prevents the metal from coming in contact with the skin.

An ingenious application of the spheroidal condition of liquids is sometimes made in the glass-house in blowing globes or cylinders of large size: the globular form is first given by means of open hemispherical wooden moulds; and, to prevent them from being burnt, the workman pours into them a small quantity of water, which protects the wood, and, assuming the spheroidal state, does not cool the molten glass.

ECBALIUM OFFICINARUM, (Richard), is the name now given to the plant, the unripe fruit of which furnishes the *elaterium* of the Materia Medica. Its familiar name is Wild Cucumber, or Asses' Cucumber, indicative of its appearance, and hurtful properties to those who incautiously employ it. Its medical or professional employment will generally be sufficiently careful—but as its incautious handling even may lead to serious, if not fatal effects, it is proper that these should be guarded against. The exhalation from the fruit, which can readily be absorbed through the human skin, is capable of producing as strong effects as a dose of the substance taken by the mouth. An instance is recorded where a small portion of the plant, with only one or two small fruits on it, carried in the hat for not more than an hour, produced violent headache, vomiting, and purging, followed by a degree of exhausting depression, almost fatal.

The other points connected with this plant are treated of under MORMODICA in the NAT. HIST. DIV., and under ELATERIN, in ARTS AND SCI. DIV.

ECCENTRIC IN MACHINERY. [EXCENTRIC.]

ECCLESIASTES, or THE PREACHER, a canonical book of the Old Testament, placed after the Proverbs and before the Song of Solomon. The English title is adopted from that in the Greek Septuagint ('Εκκλησιαστὴς, *Ecclesiastes*), which is a translation of the Hebrew title קחלח, *Koheleth*, that is, one who calls together or calls out to an assembly—a public declaimer or preacher. A review of the various learned interpretations of this term is given in Mr. Holden's work on Ecclesiastes, p. 31. Widely different opinions have been expressed by many Biblical critics concerning the author, date, and design of this portion of the Bible. The general supposition that Ecclesiastes was written by Solomon is apparently warranted by the passages i. 1, 12, 16, ii. 4–9, which designate the author as the son of David, king of Israel, and the greatest possessor of wealth and wisdom in Jerusalem. The writers of the Talmud, and Rabbi Kimchi attribute this book, as well as Proverbs and the Song, to King Hezekiah or the prophet Isaiah. The Rev. G. Holden, in his 'Attempt to Illustrate the Book of Ecclesiastes,' ably contends for its authorship by Solomon, in his old age, when he had repented of his former practices, and says, "Many parts of the work itself corroborate this opinion. The acknowledgment of numerous follies and delusions implies that it was composed after the author had apostatised from Jehovah, and had subsequently repented of his past misconduct." This view seems by far the best supported by the internal evidence of the book; notwithstanding the opposition founded on style, and certain asserted minute inconsistencies by many German, French, and English authors. Dr. Adam Clarke ('Preface to Ecclesiastes,' in his ed. of the Bible) asserts that the traditionary notion entertained by the Jews and many Christian divines, as Jerome, Huet, Michaelis, &c., that Ecclesiastes was written by Solomon in his old age, after recovering from idolatry and sensuality, is an assumption which never has been nor can be proved to be true; for since it was "when Solomon was *old*, that his heart was turned away after other gods by his 700 wives and 300 concubines" (1 Kings, ii. 3 and 4); and as he died about the age of sixty, the supposition of a final period of philosophical and pious contrition is not warranted by probability. "The language," says the same divine, "puzzles me not a little; Chaldaisms, Syriasms, and Chaldee words are frequent, and the style is that of the authors who lived at or after the captivity." Bishop Lowth remarks that the style is peculiar; the diction low, exceedingly obscure, loose, unconnected, and resembling conversation. ('Prælect.' 24.) The general opinion of the commentators, that the design of the book is to inquire about the *supreme good*, and to show that it consists in religious wisdom, is adopted by Mr. Holden, with the idea, also, of its consisting of two divisions: the first, to verse 10 of chap. vi., being occupied in setting forth the vanity of all the labours and enjoyments of human life; the second, in eulogising religious wisdom and describing its nature and effects. This wisdom has nothing sensual; it is holy and spiritual; and forms the ultimate good for creatures who are to be responsible for their actions. The book was included in the canon of the Hebrew Scriptures alluded to and sanctioned by our Saviour in Luke xxiv. 44, and by St. Paul in 2 Timothy iii. 16.

ECCLESIASTICAL COMMISSIONERS. The Ecclesiastical Commissioners are a body corporate, created by the statute 6 & 7 Will. IV. c. 77, for certain purposes and with certain powers therein named. The great inequalities in the extent and income of the dioceses of England and Wales, in the duties and receipts of the cathedral and collegiate bodies, and in the extent of parishes and the annual value of the benefices of the Church of England, after long and angry comments, gave rise in 1835 to the issue of two commissions, directing the persons named therein to consider the state of the dioceses with reference to the amount of their revenues, and the more equal distribution of episcopal duties; and of the several cathedral and collegiate churches, with a view to the suggestion of such measures as might render them conducive to the efficiency of the Established Church; and further, to devise the best mode of providing for the cure of souls with special reference to the residence of the clergy on their respective benefices. These commissioners made four reports, recommending various alterations, and the appointment of permanent commissioners, for the purpose of preparing and laying before the sovereign in council such schemes as should appear to them to be best adapted for carrying those recommendations into effect; the Crown being empowered to make orders ratifying such schemes, having the full force of law. The statute above mentioned was passed in consequence; and under its provisions a great many beneficial alterations have been and are being effected. The recommendations contained in the four reports of the original commissioners have also been carried out, with certain modifications and amendments, to which the sanction of Parliament was required and obtained (see 1 & 2 Vict. cc. 30, 106, 108; 2 & 3 Vict. cc. 9, 14; 3 & 4 Vict. c. 113; 4 & 5 Vict. c. 39; 6 & 7 Vict. c. 77; 10 & 11 Vict. cc. 98, 108; 13 & 14 Vict. c. 41; 16 & 17 Vict. c. 50). The chief features of the alterations thus effected are the equalisation of the territorial extent of the dioceses, the creation of the new sees of Ripon and Manchester, and the union of the sees of Gloucester and Bristol. The revenues of the sees have also been equalised, by augmenting the income of the smaller out of the revenues of the larger. Cathedral and collegiate bodies have also been regulated. The powers and constitution of the Ecclesiastical Commissioners have been amended by the stat. 3 & 4 Vict. c. 113, s. 78: and by the appointment of Church Estates Commissioners, who are *ex officio* members of the Ecclesiastical Commission (13 & 14 Vict. c. 94; 14 & 15 Vict. c. 104; 19 & 20 Vict. c. 74); and, lastly, by the transfer to them of the powers of the Church-Building Commissioners.

ECCLESIASTICAL COURTS. Tribunals in which the archbishops and bishops exercise jurisdiction over matters within their control. Long previous to the Conquest, during the reigns of the Danish and Saxon kings, the bishops and clergy held synods or councils. (See Sir H. Spelman, Wilkins' 'Concilia,' Johnstone's 'Canons and Constitutions.') The bishops also assisted as counsellors in the national Witten-gamotte (the antetype of our parliament), and assisted in common with the shire-reeves, or sheriffs, in the administration of justice. Shortly after the Conquest, William promulgated a charter, whereby he severed civil and ecclesiastical jurisdiction, thereby creating for the latter a distinct and independent authority, and a law was passed to the effect that no bishop should take cognisance of secular matters, and that no lay tribunal should take cognisance of matters affecting the clergy or relating to the church. Hence may be traced the origin of the present several ecclesiastical courts throughout the land, and their independent jurisdiction has from time to time been confirmed by canons, emanating it is true from ecclesiastical authority, but applied by legislative enactment, sometimes restraining their power, at others confirming and enlarging it. (For example, see 13 Edw. I. st. 4, c. 1; 9 Edw. I. st. 1, c. 1; 50 Edw. III. c. 4; 2 & 3 Edw. VI. c. 13; and Coke's 'Inst.,' 663.)

It was the policy of the early English monarchy to foster the power of the church as a check to that of the barons or nobles of the land, who struggled to interpose the principles of the feudal law as a barrier to regal assumption. But the sovereign found that the ecclesiastical authority, culminating as it did in the Pope of Rome, he being the ultimate appellee, interfered with, if it did not usurp, his function of government, in as much as it declared the clergy amenable to the ecclesiastical authority alone, be their offence what it might; and thus Henry II. caused to be framed, as a check, the 'Constitutions of Clarendon,' whereby the clergy were made amenable to the secular power in secular matters. But the ecclesiastical courts still retained full power to adjudicate upon all matters affecting the clergy in their peculiar vocation, and also upon all spiritual matters affecting the laity (which, in their language, concerned the health of the soul). And thus, even after the Reformation, numbers of persons, even in Protestant times, were sent to the dungeon and the faggot for heresy or unsound doctrine, by these tribunals, from which there was no appeal, and where ofttimes prejudice and zeal usurped the province of justice.

As far back as July, 1830, a Commission was appointed to inquire into the practice and jurisdiction of the ecclesiastical courts in England and Wales. The report of the Commissioners, which was presented in 1831, was signed by the archbishop of Canterbury, and three of the bishops, the two chief justices, the chief baron, and several other persons of authority and eminence. This report gives the most correct and authentic account which exists of—1. The nature of the ecclesiastical courts; 2. Of the course of proceeding in ecclesiastical suits; and 3. The nature of the processes, practice, and pleadings of the ecclesiastical courts. Other commissions were appointed by the Crown, and bills have been brought into Parliament from time to time; and in consequence a great change has at length been effected with regard to the jurisdiction of the ecclesiastical courts: they no longer can take cognisance of testamentary causes, nor do they any longer retain the right to grant probate of a will or letters of administration. The act of Parliament, 20 & 21 Vict. c. 77, which came into operation on the 11th of January, 1858, has transferred the voluntary and contentious jurisdiction in relation to the granting or revoking wills and letters of administration to a newly constituted court, called the "Court of Probate," its functions to be exercised in the name of the Sovereign, in such place as the

Sovereign in council shall from time to time appoint. At present the court sits in Westminster Hall. So also by the 20 & 21 Vict. c. 85, are they deprived of their jurisdiction over questions of marriage and divorce. The power of granting judicial separations (similar to those *à mensâ et thoro*, but more remedial in their effect) is now vested in the crown, as also the power of dissolving a marriage. [DIVORCE.] The court styled Her Majesty's Court for Divorce and Matrimonial Causes alone administers matrimonial law, subject to an appeal to the House of Lords. The archbishops and bishops, however, still retain their privilege of granting licenses to marry without publication of banns.

By these enactments the ecclesiastical courts have lost the most important of their functions, but they still retain exclusive cognisance of all spiritual matters concerning the clergy, such as the preaching or publishing of unsound doctrine, that is, anything repugnant to the articles or doctrine of the Church of England; and also their discipline, that is, their moral conduct and mode of life; also whether the performance of the church service is at variance with the injunctions of the rubric. (The Church Discipline Act, 3 & 4 Vict., c. 86, defines and regulates the mode of procedure against offending clergymen, although its provisions are by no means perfect in attaining its object). They also can inquire into the refusal of a bishop to institute the presentee of a patron to a living by the form of a proceeding known as a *duplex querela*; non-payment of church-rates, repair of churches and faculties for their alteration, the extension and violation of graveyards, or the removal of bodies; the right to pews, whether merely a possessory right or one confirmed by title or presumption; brawling, that is, violent behaviour in the church; non-payment of tithes (where there is no modus or prescription, in which case the matter is for the temporal courts); simony, also a matter for temporal cognisance, as regards a layman. These are questions within the jurisdiction of the ecclesiastical courts, to which might be added incontinence, swearing, drunkenness, absence from church, and other matters which, in former times, it was deemed the duty of Mother Church to restrain and punish; but such proceedings have fallen into desuetude.

The ordinary ecclesiastical courts are: 1. The *Provincial Courts*, being, in the province of Canterbury, the Court of Arches, or Supreme Court of Appeal, the jurisdiction of which is settled by 23 Hen. VIII. c. 9, and the Court of Peculiars; and in the province of York, the Chancery Court. 2. The *Diocesan Courts*, being the consistorial court of each bishop, exercising general jurisdiction; the court or courts of one or more commissaries appointed by the bishop, or fixed by custom, in certain dioceses, to exercise general jurisdiction, within prescribed limits; and the court or courts of one or more archdeacons or their officials, who exercise general or limited jurisdiction, according to the terms of their patents, or to local custom. 3. There are also *Peculiars* of various descriptions in most dioceses, and in some they are very numerous: royal, archiepiscopal, episcopal, decanal, sub-decanal, prebendal, rectorial, and vicarial.

The Provincial Courts of the archbishop of Canterbury, and the archbishop of York, are independent of each other; the process of one province does not run into the other, but is sent by a requisition from the court of one province to the local authority of the other, for execution, when it is necessary. The appeal from each of the provincial courts lies to the sovereign, represented by the Judicial Committee of Privy Council; but before the passing of the statute 2 & 3 Will. IV., c. 92, a commission issued under the Great Seal in each individual case of appeal, to certain persons or delegates, to hear and determine the matter in contest. [DELEGATES, COURT OF.]

Of the three Archiepiscopal Courts of Canterbury, the Arches Court is the first [ARCHES, COURT OF,] (deriving its title from the place where it originally sat, Bow Church, *St. Mary de arcubus*). It is presided over by a functionary, styled the "Dean of the Arches," appointed by the archbishop of Canterbury. This court exercises appellate jurisdiction from each of the diocesan and most of the peculiar courts within the province. It may also take original cognisance of causes by letters of request, from each of those courts.

The Court of Peculiars, thirteen of which are in the Province of Canterbury, is the third Archiepiscopal Court of Canterbury, it takes cognisance of all matters arising in those Peculiars, among which are the Deaneries of London, Rochester, and Winchester; and some others, over which the archbishop exercises ordinary jurisdiction, and which are exempt from and independent of the several bishops within whose dioceses they are locally situated.

The province of Canterbury includes twenty-one dioceses. The Archbishop's Court (that is, the Arches Court), does not exercise ordinary episcopal jurisdiction, and therefore a commissary is appointed for that purpose, which stands on the same footing as the ordinary consistory of a bishop. Thus the ordinary episcopal jurisdiction is exercised by the commissary, in the same manner as in other dioceses.

The province of York includes five dioceses, besides that of Sodor and Man, the archiepiscopal jurisdiction is exercised therein much in the same manner as in the province of Canterbury.

The Diocesan Courts take cognisance of all matters arising locally within their respective limits, with the exception of places subject to peculiar jurisdiction. They may decide matters of spiritual discipline; suspend clergymen from their office, and administer the other branches of ecclesiastical law; but in matters of importance the case is generally sent to the Arches Court by letters of request.

The Archdeacon's Court is generally subordinate, with an appeal to the Bishop's Court; though in some instances it is independent and co-ordinate.

The Archdeacons' Courts, and the various Peculiars already enumerated, in some instances take cognisance of all the ecclesiastical matters arising within their own limits, though the jurisdiction of many of the peculiar courts extends only to a single parish: the authority of some of them is limited to a part only of the matters that are usually the subject of ecclesiastical cognisance; several of the peculiars possess voluntary but not contentious jurisdiction.

The total number of courts which exercise any species of ecclesiastical jurisdiction in England and Wales is 372, which may be classed as follows:—

Provincial and diocesan courts	36
Courts of bishops' commissaries . . .	14
Archidiaconal courts	37
Peculiar Jurisdictions.	
Royal	11
Archiepiscopal and episcopal	44
Decanal, subdecanal, &c.	44
Prebendal	88
Rectorial and vicarial	63
Other peculiars	17
Courts of lords of manors	48

The amount of compensation awarded to the judges, registrars, and other officials of the several courts abolished by the late Acts, taking the half of an average of fees, &c. for the five years preceding 11th January, 1858, amounted, for England to 40,950*l.* 14*s.* 8*d.*, and to the proctors 60,304*l.* 9*s.* 9*d*; for Ireland, judges, &c., 7719*l.* 9*s.* 8*d.*; proctors, 8717*l.* 18*s.* 2*d.*, making in the whole 117,782*l.* 12*s.* 3*d.*, payable in the shape of annuities.

The canon law has been practised in the ecclesiastical courts as a distinct profession for upwards of three centuries; but owing to recent changes by taking from those courts their testamentary and matrimonial jurisdiction, it is scarcely probable that any body of professional men will henceforth devote themselves exclusively to those tribunals. The courts, together with that of the Admiralty, have hitherto sate in the College of Advocates at Doctors' Commons, where also, in close contiguity to the court, have resided the judges and advocates. The site of the building was purchased by some members of this body in 1567. [DOCTORS' COMMONS.] The members of the society were incorporated in 1768 by a royal charter, under the name of 'The College of Doctors of Laws exercent in the Ecclesiastical and Admiralty Courts.' The proctors discharge duties similar to those of solicitors and attorneys in other courts. [PROCTOR.]

The course of proceeding in these courts is as follows:—The mode of commencing the suit, and bringing the parties before the court, is by a process called a Citation, or summons. This citation, in ordinary cases, is obtained as a matter of course, from the registry of the court, and under its seal; but in special cases, the facts are alleged in what is termed an act of court, and upon those facts the judge or his surrogate decrees the party to be cited; to which, in certain cases, is added an intimation, that if the party does not appear, or appearing does not show cause to the contrary, the prayer of the plaintiff, set forth in the decree, will be granted. The party cited may either appear in person, or by his proctor, who is appointed by an instrument, under hand and seal, termed a proxy. The proctor thus appointed represents the party, acts for him and manages the cause, and binds him by his acts.

The mode of enforcing all processes, in case of disobedience, is by pronouncing the party cited to be contumacious; and if the disobedience continues, a significavit issues, upon which an attachment from Chancery is obtained, to imprison the party till he obeys. In cases where some act is required to be done by the party cited, the compulsory process is enforced; but in some cases, where no act is necessary to be done by the party cited, the plaintiff may proceed in pœnam contumaciæ, and the cause then goes on *ex parte*, as if the defendant had appeared. The party cited, to save his contumacy, may appear under protest, and may show cause against being cited; such as, that the court has no jurisdiction in the subject-matter, or that he is not amenable to that jurisdiction: this preliminary objection is heard upon petition and affidavits; and either the protest is allowed, and the defendant is dismissed, or the protest is overruled, and the defendant is assigned to appear absolutely; and costs are generally given against the unsuccessful party. Each party may appeal from the decision on this preliminary point; or the defendant, in case the judge decides against him on the question of jurisdiction, and on some other questions, may apply to a court of law for a prohibition.

The form of the pleadings is next to be described. These are intended to contain a statement of the facts relied upon and proposed to be proved by each party in the suit, the real grounds of the action, and of the defence.

Causes, in their quality, are technically classed and described as plenary and summary, though in modern practice there is substantially little difference in the mode of proceeding. All causes in the Prerogative Court are summary.

The first plea bears different names in the different descriptions of causes. In criminal proceedings, the first plea is termed the Articles; in form, it runs in the name of the judge, who articles and objects the facts charged against the defendant; in plenary causes, not criminal, the first plea is termed the Libel, and runs in the name of the party or his proctor, who alleges and propounds the facts founding the demand. Every subsequent plea, in all causes, whether reponsive or rejoining, and by whatever party given, is termed an Allegation.

Each of these pleas contains a statement of the facts upon which the party founds his demand for relief, or his defence; they resemble the bill and answer in equity, the allegation is divided into separate positions or articles: the facts are alleged under separate heads, according to the subject-matter, or the order of time in which they have occurred. Under this form of pleading the witnesses are produced and examined only to particular articles of the allegation, which contain the facts within their knowledge in private by an appointed examiner of the court; their evidence is taken down and produced on the hearing; a notice or designation of the witnesses is delivered to the adverse party, who is thereby distinctly apprised of the points to which he should address his cross-examination of each witness, as well as the matters which it may be necessary for him to contradict or explain by counter-pleading.

Before a plea of any kind, whether articles, libel, or allegation, is admitted, it is open to the adverse party to object to its admission, either in the whole or in part: in the whole, when the facts altogether, if taken to be true, will not entitle the party giving the plea to the demand which he makes, or to support the defence which he sets up; in part, if any of the facts pleaded are irrelevant to the matter in issue, or could not be proved by admissible evidence, or are incapable of proof. These objections are made and argued before the judge, and decided upon by him, but his decision may be appealed from. For the purpose of the argument, all the facts capable of proof are assumed to be true; they are however so assumed merely for the argument, but are not so admitted in the cause; for the party who offers the plea is no less bound afterwards to prove the facts, and the party who objects to the plea is no less at liberty afterwards to contradict the facts. If the plea is admitted, the further opposition may be withdrawn: if the plea is rejected, the party who offers it either abandons the suit, or appeals against the rejection, in order to take the judgment of a superior tribunal. When a plea has been admitted, a time, or term probatory, is assigned to the party who gives the plea, to examine his witnesses; and the adverse party is assigned, except in criminal matters, to give in his answers upon oath, to his knowledge or belief of the facts alleged. The defendant may proceed then, if he thinks proper, or he may wait until the plaintiff has examined his witnesses, to give an allegation controverting his adversary's plea. This responsive allegation is proceeded upon in the same manner; objections to its admissibility may be taken, answers upon oath be required, and witnesses examined. The plaintiff may, in like manner, reply by a further allegation; and on that, or any subsequent allegation, the same course is pursued.

In taking evidence, the witnesses are either brought to London to be examined, or they are examined by a commission near their places of residence. Their attendance is required by a Compulsory, somewhat in the nature of a subpœna, obedience to which is enforced in the same way as in other cases of contumacy. The examination is by depositions taken in writing and in private by examiners of the court, employed for that purpose by the registrars. The examination does not take place upon written interrogatories previously prepared and known; but the allegation is delivered to the examiner, who, after making himself master of all the facts pleaded, examines the witnesses by questions which he frames at the time, so as to obtain, upon each article of the allegation separately, the truth and the whole truth, as far as he possibly can, respecting such of the circumstances alleged as are within the knowledge of each witness. The cross-examination is conducted by interrogatories addressed to the adverse witnesses, and when the deposition is complete, the witness is examined upon the interrogatories delivered to the examiner by the adverse proctor, but not disclosed to the witness till after the examination in chief is concluded and signed, nor to the party producing him till publication passes; and each witness is enjoined not to disclose the interrogatories, nor any part of his evidence, till after publication. In order that the party addressing the interrogatories may be the better prepared, the proctor producing the witness delivers, as before stated, a designation, or notice of the articles of the plea on which it is intended to examine each witness produced.

The examination and cross-examination of witnesses are kept secret until publication passes; that is, until copies of the depositions may be had by the adverse parties, after which either party is allowed to except to the credit of any witness, upon matter contained in his deposition. The exception must be confined to such matter, and not made to general character, for that must be pleaded before publication; nor can the exception refer to matter before pleaded, for that should be contradicted also before publication. The exception must also tend to show that the witness has deposed falsely and corruptly. The exceptive allegations are proceeded upon, when admitted, in the same manner as other pleas. They are not frequently offered, and are always received with great caution and strictness, as they tend more commonly to protract the suit and to increase expense than to afford substantial information in the cause. It is, however, in the power of the court to allow further pleading by way of additional articles; and if new circumstances of importance are unexpectedly brought out by the interrogatories, the court will, in the exercise of its discretion, allow a further plea after publication. This may also be permitted in cases where facts have either occurred or come to the knowledge of the party, subsequently to publication having passed.

The evidence on both sides being published, the cause is set down for hearing. All the papers, the pleas, exhibits (or written papers proved in the cause), interrogatories, and depositions, are delivered to the judge for perusal before the case is argued by counsel. All causes are heard publicly in open court; and as in other courts, the counsel state their respective cases. The evidence is then read, unless the judge signifies that he has already read it, and even then particular parts are read again if necessary. The judgment of the court is then pronounced upon the law and facts of the case; and in doing this, the judge publicly, in open court, assigns the reasons for his decisions, stating the principles and authorities on which he decides the matters of law, and reciting or adverting to the various parts of the evidence from which he deduces his conclusions of fact, and thus the matter in controversy between the parties becomes adjudged.

The execution of the sentence, in case there be no appeal interposed, is either completed by the court itself, according to the nature of the case, and execution is enforced by the process of contumacy, significavit, and attachment; but this can only be done by calling in the aid of the Court of Chancery. Ecclesiastical courts, not being courts of record, have no power to commit of their own authority. The question of costs in these courts is, for the most part, a matter in the discretion of the judge, according to the nature and justice of the case; and the reasons for granting or refusing costs are publicly expressed at the time of giving the judgment.

Attempts were made more than three centuries ago to remedy the defects of the ecclesiastical courts. The earliest efforts of this kind were directed to the peculiar jurisdictions. Some of these jurisdictions extend over large tracts of country, and embrace many towns and parishes; others comprehend several places lying at a great distance from each other; and some only include one or two parishes. The jurisdiction to be exercised in these courts is not defined by any general law, and it is often difficult to ascertain to what description of cases the jurisdiction of any particular court extends. The commissioners appointed to revise the ecclesiastical laws, in the reigns of Henry VIII. and Edward VI., recommended that the power of the bishop, in matters of discipline, should extend to all places in the diocese, notwithstanding the exemptions and privileges of Peculiars. In the reign of Queen Elizabeth, it was proposed or talked of in convocation that parliament should be applied to, to subject peculiar and exempt rights and jurisdictions of what had belonged to monasteries to the diocesan. Nothing, however, appears to have been done until, in 1857, the 20 & 21 Vict. c. 77, and c. 85, were passed, directing the sweeping changes before named. For full information on the constitution and practice of these courts, see the report of the Ecclesiastical Commissioners published in 1832, and Coote's 'Ecclesiastical Practice.'

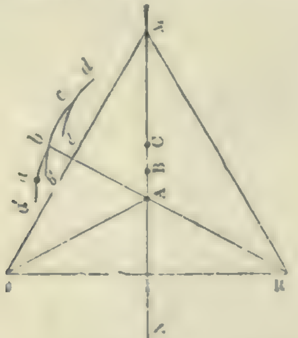
ECCLESIA'STICUS, or THE WISDOM OF JESUS THE SON OF SIRAC, an apocryphal book of the Old Testament. It is stated to have been originally written in Syro-Chaldaic, by Jesus, the son of Sirac, a learned Jew, who travelled in pursuit of knowledge 130 years B.C. It was translated into Greek for the use of the Jews of Alexandria, by the grandson of the author, or rather compiler, for it is evidently a collection of fragments, written at different times and on various occasions, consisting of meditations and proverbs relating to religion, morals, and the general conduct of human life. But though it is manifest that no methodical plan or arrangement was observed in the composition, the commentators remark that the whole will admit of division into three parts. The first extends to the end of chap. 43, and is occupied in the commendation of wisdom and the statement of moral precepts. The second celebrates the virtues of the patriarchs and prophets of the Jews, and extends to the end of chap. 49. The third part is comprised in the 50th and concluding chapter, and consists of a prayer or hymn, exhorting mankind to the pursuit of wisdom. These meditations display much acuteness of thought, with propriety of diction, and occasionally poetical eloquence. They closely resemble the numerous other oriental proverbs, and especially the collection attributed to Solomon. In the western Christian church this book was highly esteemed; the council of Carthage made it canonical, as the fifth book of Solomon, and the council of Trent confirmed the decision. It was also introduced by the early Protestant reformers into the liturgy of the church of England.

Addison, in the 68th number of the Spectator, observes, that were this collection issued under the name of Confucius, or one of the sages of Greece, it would be regarded as one of the most brilliant moral treatises ever published. The opinion which attributes it to Solomon is falsified by several allusions to the captivity, showing that some parts at least were written under the monarchs of Babylon (c. 47, &c.), 400 years subsequent to the reign of Solomon. The Greek fathers frequently cite the book of Ecclesiasticus as *ἡ Ἰησοῦ Σοφία*, the Wisdom of Jesus; *Πανάρετος Σοφία*, the Excellent Wisdom; and *Λόγος*, the Rational Discourse. The Latin fathers named it Ecclesiasticus, or the Book of the Church, from its being then appointed to be read in churches. A Syriac and an Arabic version are extant. The Latin version, which is supposed to be of the first century, contains numerous words adopted from the Greek, but differs much from the present Greek text.

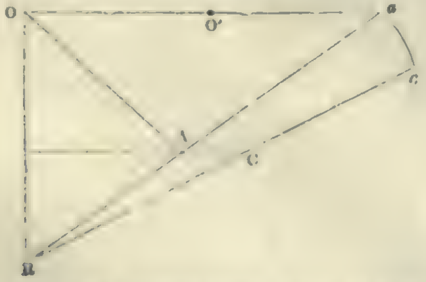
(*Ecclesiasticus, or the Book of the Church*, by Luke Howard, F.R.S., 1827; Dalrymple, Lord Hailes, *Wisdom of Solomon, or Ecclesiasticus*, 1755; Sonntag, *Comment. de Jesu Siracidæ Ecclesiastico*, 4to., 1792; Bretschneider, *de lib. Jesu Siracidæ* (prolegom. pp. 10–32), dates the original compilation 180 B.C.; Horne's *Introduct. to the Bible*, vol. iv.)

E'CHEVIN, the name given under the old French monarchy to the municipal magistrates of various cities and towns. At Paris there were four échevins and a prévôt des marchands, whose jurisdiction extended over the town and adjacent territory; in the other towns there was a maire and two or more échevins. In the south of France the same officers were called by other names, such as consuls in Languedoc and Dauphine, capitouls at Toulouse, jurats at Bordeaux. The last name, that of jurats, is retained in some of the English municipalities. They tried minor suits, laid the local duties or octroi upon imports, had the inspection of the commercial revenues and expenditure, as well as the superintendence of the streets, roads, and markets, the repairs of public buildings, &c. The name échevins seems to have been derived from scabini, a Latin word of the middle ages, which was used in Italy under the Longobards, and in France, Flanders, and other countries under the Carlovingian dynasty. In Holland they are called schepens. The scabini were the assessors to the counts or missi dominici, appointed by the monarch to administer a province or district; and they were chosen among the local inhabitants. Afterwards, when charters were given to the communes, the municipal magistrates elected by the burgesses assumed also the name of scabini or échevins. (Ducange, 'Glossarium.')

ECHO. (ἠχὼ, ἦχος, *sound*). When sonorous undulations are propagated from any origin through the elastic medium of the air, the spherical wave-like surface then conveys the sound through the circumjacent space, and moves from its origin and centre with a velocity of about 1125 feet in a second, at the ordinary atmospheric pressure and temperature; for the velocity of undulations propagated through elastic media depends only on their indices of elasticity and not on their intensity. [ACOUSTICS.]



Suppose the point O to be the origin of a sound which in its progress encounters a plane obstacle NM; if this plane be sufficiently extended, a point M may be easily found which the sound will have just reached at the end of a given time. The waves which have previously reached the nearer points A, B, C, being precluded from advancing, are there reflected according to the usual law of reflection of light, that is, new spherical undulations *a'ab*, *b'bc*, *c'cd* are generated from A, B, C as centres, and their radii at the moment we have spoken of are respectively A*b* = OM — OA, B*c* = OM — OB, C*d* = OM — OC, and it is easily seen that all these spherical surfaces originating from A up to M and existing simultaneously, may be exactly enveloped by a single portion of a spherical surface of which the centre is placed in a position R corresponding to O in respect to its distance from NM, but at the opposite side of the obstacle; this spherical surface, of which the radius is RM, is the true returning wave at that moment, and being impressed on the auditory organs, so as to be distinguished from the original sound, is called the *echo*.



When a sound originates at a point O, and is reflected by a plane obstacle A C, the reflected pulsation of the air occupies the space of a conical frustum *a* A C *c*, the vertex of the cone R being situated symmetrically with O at the opposite side of A C. In order that a person may hear the echo of his own sounds, it is therefore necessary that his situation may be a point O' in a perpendicular to A C; and that a second person may hear the echo of the voice of another at O, he must be situated in the frustum *a* A C *c*, so that the angles of incidence and reflection of the sound which reaches his ear may be equal, as in the case of the reflection of light, and the impact of perfectly elastic bodies [LIGHT; COLLISION]; in both cases the distance from A C must be sufficiently great to distinguish between the original and the reflected sound.

The echo of a continued sound or note may be heard in the inverse order of time to that in which it was generated, provided the origin of the sound moves more rapidly towards the hearer than the rate at which sound travels. Thus a flash of lightning moving towards a person will produce a roll of thunder which, echoed by clouds, will be heard as it were backwards; but if the direction of the flash be such that the points of its course are nearly equidistant from the auditor, an instantaneous and intensely loud clap will be substituted for a continued roll.

The murmuring sound produced by the discharge of great guns is the succession of echoes from the particles of vapour floating in the atmosphere, and when the discharge is effected under a dense cloud, the echoes are stronger and better reflected, and a noise resembling a thunder-roll may then be heard. The whizzing of a bullet is attributed to its impinging in a state of rapid rotation on particles of vapour.

The time intervening between the primitive sound and its echo has sometimes been employed in determining the distance from the observer to the reflecting object, allowing 571 feet for each intermediate second of time; but like all methods dependent more on individual judgment than mechanical measurement, this process must be liable to considerable irregularities.

When several objects reflect sound, the number of echoes is greatly multiplied, not only from the primary echoes of each, but also from secondary and tertiary echoes by second and third reflections of returning waves against the reverberatory obstacles; each re-echo consists of only portions or frusta of the preceding; their intensities therefore diminish, and they gradually die away upon the ear, in the same manner that the images become obscure and by degrees imperceptible in consequence of the diminution of light when we look between two opposite and parallel plane mirrors. The reflecting plane, however, must be at a great distance in order to produce polysyllabic echoes. At Woodstock is one repeating from seventeen to twenty syllables, and the Swiss mountaineers sing their *Ranz des Vaches*, so that the echoes form an accompaniment to the tune itself.

The first echo heard in such circumstances is by no means necessarily the loudest. Taking any ellipse of which one focus is the origin of the sound and the other the place of the auditor, it is a well-known property of this curve that right lines drawn from the foci to any point in it make equal angles with the tangent at that point. Conceive now this ellipse to rotate round the line joining the foci so as to form a prolate spheroid, then sound emanating from one focus and reflected by a portion of the surface will be directed after reflection to the other, and its intensity will depend on the solid angle subtended at the focus by the reflecting body. Each echoing body may be conceived as a portion of such a spheroidal surface, taking a large axis major to comprehend the more distant bodies; and since the sum of the solid angles subtended by the more distant reflectors may be greater than those given by the nearer, the echo produced by them, though not reaching the ear so soon as that of the nearer, may, under such circumstances, be louder. We must, however, bear in mind in our estimate that this intensity has a source of diminution in the increase of distance. This case frequently occurs in places encompassed by chains of mountains, as at Killarney and the Welsh lakes, &c.

When the succession of echoes from several bodies is sufficiently rapid, a continued sound or note may be produced, though the original sound was merely momentary; and when not sufficiently rapid for this purpose, a clamorous noise is produced, and hence Echo with her thousand tongues and babbling propensities has furnished matter for poetic imagination from Ovid to Shakspere. Hence, Echo has been called the "shadow of a sound," "a voice without a mouth, and words without a tongue." Echo too, though represented as a female, never speaks until she is spoken to, and at every repetition of what she has heard, continues to make it less, an example recommended to the special imitation of scandal-mongers. As a single *ha!* may be converted into an imitation of a stunning laugh, the romantic and echoing regions inhabited by the Scandinavian races materially assisted their untutored imaginations in attributing this appalling music to the aërial revelries of invisible hags or witches. The blow of a hammer against one side of a parallel fissure in a rock, sometimes produces echoes sufficiently rapid in succession to give the tone of a bell, as in the Bell-rock at Tonbridge-wells.

But when, as in the case of the electric fluid, the original cause of sound may be said to exist simultaneously through an extensive tract of an excited atmosphere, a sound perfectly continuous and majestic is produced in the thunder-roll, which may frequently be heard again echoed by neighbouring clouds, or awfully prolonged by repeated reflections from an amphitheatre of mountains.

A similar effect of rapidly repeated echoes may be perceived in the prolonged tread and ringing sounds which we hear when walking in stillness through long galleries, cloisters, and other narrow passages with parallel sides, particularly when the air is confined; but hangings and carpetings, yielding to the impulse of the sonorous waves, or stifling them by a multitude of interior reflections, together with open windows or much furniture, diminish these effects to a great extent.

The distribution of sound in public edifices, so that the echoes may be most advantageously brought to strengthen the original sound, is a subject practically deserving of much attention. For some sensible observations on the errors of architects in this respect, we must refer to Sir J. Herschel's treatise on 'Sound.' Certainly the unlucky error of placing the confessional in the cathedral of Girgenti in a focus conjugate to another, which happened to be an unenclosed part of the church, by which Echo was instrumental in informing a husband of the infidelity of his spouse; and the parabolic reflector of a late ingenious clergyman at Cambridge, which had the effect of completely stunning him, however impartially his voice was distributed to his congregation, are not inconveniences of such common occurrence as those contrivances by which a part of an audience in a church or theatre possesses a monopoly, while the remainder witness the ceremony or performance in dumb show.

A ludicrous anecdote, mentioned by Lord Bacon, of a Frenchman calling out Satan, and being answered *Va-t'en*, led him to assert that the letter S was not echoed, and this assertion has been copied by several authors. The fact is, that S being in a great measure a breathing, the distance necessary for the production of a distinct echo is too great to render it audible, owing to its small intensity; but when its echo is taken at a small distance, the effect is to increase the sound, and this disagreeable prolongation is very perceptible in churches whenever persons in repeating the service make use of this letter. The whispering gallery of St. Paul's is another instance of this error, for a low whisper uttered at one end is conveyed by successive reflections along its curved roof, and being again concentrated at the other end, may be distinctly heard, although, in such cases, it has been also attributed, not to *reflection*, but to what Mr. Scott Russell terms *lateral accumulation*, of the sonorous wave.

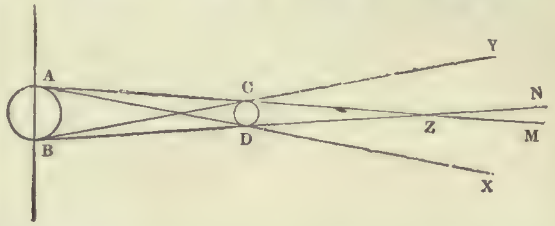
When the reflecting surfaces, instead of plane, are curved, as in caverns, grottoes, rocks, or ruined buildings, the reflected sound will be most intense at the foci, or the points which would be most enlightened *by reflection* if a luminous body were substituted in the place of the original source of sound.

Whatever may be the figure of the echoing surface, the total path traversed by a wave in a given time before and after reflection taken together is constant (and, when the time varies, is proportional to it); therefore a small portion of a plane section of the echoing surface is common also to an ellipse having one focus at the origin of sound, the other in the returning wave, and the axis major equal to the space traversed by sound in a given time. Hence, *first*, the plane sections of the returning wave are the loci of the second foci of a series of ellipses, having a common focus and equal axes major, all touching the section of the echoing surface; and, *secondly*, the figure of an obstacle necessary to produce a given wave will be found by taking the curve which touches a series of ellipses having their second foci in this wave surface and their first focus and axis major as before: this should, however, strictly speaking, be confined to surfaces of revolution.

Lastly, M. Colladon has found from his experiments, that if sonorous undulations excited within a fluid impinge very obliquely on its surface, they do not emerge, but are *internally* reflected, as in the case of light, forming thus an echo within the fluid.

ECLECTICS. The name given to those philosophers who, without adopting any particular system, or dogmatising for themselves, professed to select (ἐκλέγειν) from other philosophical systems whatever they conceived most conformable to truth, and fitted those detached parts together so as to form a new whole. The notion of such a union of jarring systems seems first to have originated with the Neoplatonists, who endeavoured to settle the dispute between themselves and the Peripatetics, by the adoption of such parts of the doctrine of Aristotle as could be made to tally with their modification of the academic philosophy. This union of the Aristotelian and Platonic philosophies was attempted first by Potamo of Alexandria, whose principles were taken up and maintained by Ammonius Saccas. It may be doubted, however, if the title of Eclectics can be properly given to Potamo or Ammonius, the former of whom was in fact merely a Neoplatonist, and the latter rather jumbled together the different systems of Greek philosophy (with the exception of that of Epicurus), than selected the consistent parts of all of them. The most eminent of the followers of Ammonius were Plotinus, Porphyry, Jamblichus, Proclus, and Clemens Alexandrinus; and the ancient Eclecticism became at last little more than an attempt to reconcile Platonism with Christianity. The modern and more genuine school of Eclecticism sprung up in the 17th century, when Bacon and Descartes flourished. These philosophers, refusing to acknowledge themselves members of any particular sect, or to adopt any principle on the mere authority of their predecessors, formed systems for themselves which admitted the doctrines of any other sect without distinction, whenever those doctrines were not at variance with what their own investigation had taught them of the nature of things. But modern philosophers have since then formed themselves into new sects, and a new Eclecticism has consequently arisen in our own days, of which the originator was Hegel, and the most eminent supporter Victor Cousin; this newest Eclecticism resembles that of the Alexandrian Platonists in being rather a union of systems than a selection from them.

ECLIPSE (*ecleipsis*, *ἔκλειψις*), an astronomical phenomenon, being the disappearance of a heavenly body. This may happen in two distinct ways; either the disappearing body may be lost on account of another body coming between it and its source of light, and thus intercepting the light; or the disappearance of a body may be caused by another body coming between it and the spectator. These two sets of circumstances, though ending in the same species of phenomenon, are yet of a character so different that it will be advisable to consider the two in separate articles. We shall therefore here content ourselves with an enumeration of the various kinds of eclipses; leaving further detail, when necessary, to the articles which will be referred to.



Let us suppose a spherical body A B, which is luminous, and another, C D, the smaller of the two, which is not luminous. Let us consider first the circular sections of these bodies made by the plane of the paper, and let common tangents be drawn to these sections, four in number, namely, A X, B Y, A M, and B N. If the bodies be very distant from each other, in comparison with their bulk, then it will be sufficient for practical purposes to consider these common tangents as intersecting at A and B and C and D, the opposite extremities of two parallel diameters. If the whole figure then revolve round the line joining the centre of the two circles, the spherical bodies will be reproduced, together with the conical envelopes by which it may be seen on what the phases of an eclipse depend.

The whole space generated by the revolution of Y C D X is, in whole or in part, deprived of the light from A B. Within the space C D Z (or the cone generated by its revolution), the loss of light is total: a spectator situated within that cone sees no part of A B, and a planet which receives its light from A B cannot, when in that cone, be visible in any part of space. This is even true at the point Z; but anywhere within the cone N Z M, more or less of the border of A B is visible, and C D hides a portion of the middle of A B. If C D be small in comparison with A B, then the effect of C D to a spectator situated far off in N Z M is only the appearance of a small dark spot upon the face of A B.

Within the spaces Y C Z N and M Z D X, a part only of the face of A B is hidden from a spectator there situated, and part only of the light of A B is lost. On the lines C Y or D X the spectator imagines the two bodies A B and C D to be in contact.

The eclipses in which the disappearance takes place by the removal of the light from the body are—

1. The eclipse of the moon. [Lunar Eclipse.]
2. The disappearance of a portion of Jupiter's surface, occasioned by one of its satellites passing between it and the sun. This is usually called the transit of the satellite's shadow over the disc of Jupiter. [Jupiter.]
3. The eclipses of Jupiter's satellites. [Jupiter.]

The eclipses in which the disappearance arises from the absolute interposition of another planet are—

1. The eclipse of the sun [Solar Eclipse], meaning the eclipse of the sun by the moon.
2. The eclipse of the sun (that is, of a very small portion of the sun) by Mercury or by Venus, commonly called the *transit* of Mercury or Venus over the sun's disc. [Mercury, Transit of; Venus, Transit of.]
3. The occultation of a fixed star by the moon. [Moon.]
4. The eclipse of a portion of Jupiter by one of its own satellites, or transit of a satellite over the disc. [Jupiter.]
5. The eclipse of a satellite of Jupiter by Jupiter itself, or occultation of a satellite by the planet. [Jupiter.]

We have here mentioned such eclipses as are not unfrequent: the only additional phenomenon which we are aware of is the eclipse of a portion of the ring of Saturn by a satellite, or passage of a satellite over the ring, seen by Sir W. Herschel. The satellites of Saturn must suffer eclipses of the first kind by entering the shadows either of the planet or the ring, and of the second kind both from the planet and the ring; but these satellites are only seen with very good telescopes and under very favourable circumstances, so that their eclipses excite little public curiosity. For an account of the physical phenomena observed during eclipses of the sun and moon, see the articles, Solar Eclipse, and Lunar Eclipse.

ECLIPTIC. [Equator and Ecliptic.]

ECLOGUE. [Bucolics].

ECONOMISTS. [Political Economy.]

EDDA. [Scandinavian Mythology.]

EDDY is a circular motion of the water, either in rivers or in the sea. It exists more frequently in rivers between the proper current and the counter current; the edges of one current brushing against another giving to a small portion of the water a circular motion. But an eddy is also produced when the current, running with some violence against a rock or elevated shore, is driven back and meets in the bed of the river or on the opposite shore another obstacle to its course. In this case the eddy generally occupies the greatest part of the bed of the river, and is frequently called a *whirlpool*. Eddies occur in the sea likewise, where two currents run parallel, but in different directions, as between the Equatorial and North African current. Whirlpools also occur frequently among rocky islands near a coast. [Whirlpool.]

EDGE. [Arris.]

EDICTAL LAW. The English Equity has some resemblance to the Roman Edictal law, or Jus Prætorium or Honorarium, as it is often called. All the higher Roman magistrates (*magistratus majores*) had the *jus edicendi* or authority to promulgate edicta. These *magistratus majores* were consuls, prætors, curule ædiles, and censors. By virtue of this power a magistrate made edicta or orders, either temporary and for particular occasions (*edicta repentina*); or upon entering on his office he promulgated rules or orders, which he would observe in the exercise of his office (*edicta perpetua*). These edicta were written on a white tablet (*album*) in black letters; the headings or titles were in red. The alba were placed in the Forum, in such a position that they could be read by a stander-by ("ubi de plano recte legi posset," D. 2, 1, 7). Those edicta which related to the administration of justice had an important effect on the Roman law, and especially the Prætoria Edicta, and those of the Curule Ædiles. That branch of law which was founded on the Prætorian Edicta was designated Jus Prætorium or Honorarium, because the prætor held one of those offices to which the term Honores was applied. The edicta were only in force during the term of office of the magistratus who promulgated them; but his successor adopted many or all of his predecessor's edicta, and hence arose the expression of "transferred edicts" (*tralaticia edicta*); and thus in the later republic the edicta which had been long established began to exercise a great influence on the law, and particularly on the forms of procedure. About the time of Cicero many distinguished jurists began to write treatises on the edictum (*libri ad edictum*). Under the emperors new edicta were rarer, and in the 3rd century of our æra they ceased. Under the empire we first find the edicta of the Præfectus Urbi mentioned; but these must be considered as founded on the imperial authority (*majestas principis*), and to have resembled the imperial constitutions. (See Tacit. Ann., 6, 11; Suet. Aug., 37; Dio. Cass., 52, 21; and Dig. i. 12, and i. 28.) Under the reign of Hadrian a compilation was made by his authority of the edictal rules by the distinguished jurist Salvius Julianus, in conjunction with Servius Cornelius, which is spoken of under the name of Edictum Perpetuum. This edictum was arranged under various heads or titles, such as those relating to marriage, tutores, legata (legacies), and so on.

By the term Prætorian Edict the Romans meant the edicts of the Prætor Urbanus, who was the chief personage employed in the higher administration of justice under the republic. The edicta which related to Peregrini (aliens) were so named after the Prætor Peregrinus; and other edicta were called Censoria, Consularia, Ædilicia, and so on. Sometimes an edict of importance took its name from the prætor who promulgated it, as Carbonianum Edictum. Sometimes the Honorariæ actiones, those which the prætor or ædile by his edict permitted, and which Ulpian opposes to Actiones Civiles, just as we oppose legal to equitable remedies (D. 44, 7, 25, 2), were named in like manner from the magistrate who introduced them. Sometimes an edict had its name from the matter to which it referred. The Romans generally cited the edicta by parts, titles, chapters, or clauses of the Edictum Perpetuum by naming the initial words, as Unde Legitimi, and so on. Sometimes they are cited by a reference to their contents. Examples of these modes of citing the edictum occur in the titles of the 43rd book of the 'Digest.' (See the title 'Quorum Bonorum.') In our own law we refer to certain forms of proceedings and to certain actions in a like way, as when we say *quo warranto*, *quare impedit*, and speak of *qui tam* actions.

The Jus Prætorium is defined by Papinian ('Dig.' i. tit. i. 7) as the law which the prætors introduced for the purpose of aiding, supplying, or correcting the law (*jus civile*), with a view to the public interest. The edict is called by Marcianus "the living voice of the Jus Civile," that is, of the 'Common' law. ('Dig.' i. tit. i. 8.) The Prætorian law as thus formed (*jus prætorium*), was a body of law which was distinguished by this name from the Jus Civile, or the strict law; the opposition resembled that of the English terms equity and law. In its complete and large sense, Jus Civile Romanorum, or the law of the Romans, of course comprehended the Jus Prætorium; but in its narrower sense Jus Civile was contrasted, as already explained, with the Jus Prætorium.

The origin of the Roman edictal law is plainly to be traced to the imperfections of the old Jus Civile, and to the necessity of gradually modifying law and procedure according to the changing circumstances of the times. It was by the prætors and the prætorian courts that the improvements in the Roman law were worked out after long years of labour, by a skilful adaptation of new forms to old processes, by an equally skilful use of fictions, and especially by means of the interdictal remedies. Nor was it because it was an easier method of doing this than by direct legislation that the prætors strove to improve the law in this way, but because they were under the imperious necessity of observing that reverence for old forms and old customs which is one of the most striking characteristics of the old Roman people, and which is nowhere more visible than in the history of their jurisprudence. (See on this point, the influence of the prætors upon Roman law, Dr. Abdy's 'Historical Sketch of Civil Procedure among the Romans,' chapter ii.) Numerous modern treatises contain a view of the origin and nature of the Roman Jus Prætorium, though on some points there is not complete uniformity of opinion.

(Böcking, *Institutionen*, vol. i.; Puchta, *Cursus der Institutionen*, vol. i., p. 293; Savigny, *Geschichte des Röm. Rechts*, vol. i.; Heffter, *Die Oeconomie des Edictes, Rhein. Mus. für Juris.*, i., p. 51; E. Schrader, *Die Prätorischen Edicte der Römer*, 1815.)

EDICTS, EDICTA, one of the five sources of Roman law enumerated by Gaius (i. § 2). "The magistrates of the Roman people have authority to make edicts; but the greatest weight is given to the edicts of the two prætors, the Prætor Urbanus and the Prætor Peregrinus. In the provinces, the governors (præsides) have the same authority as the prætors (in the city). The authority of the curule ædiles, as to making edicts, is the same as that of the prætors, and in the provinces their powers are possessed by the quæstors." (On the Edict. Ædil. see 'Dig.,' xxi. tit. 1; and on the Ædilian Actions, 'Cod.' iv. tit. 58.)

It was the custom of the prætors on their accession to office to publish edicts, which were rules published for the benefit of suitors, and for the express purpose of regulating the practice of their courts during their year of office. This power of regulating the practice of their courts having been abused, especially by the custom of altering their original edict during their year of office, it was enacted by the Cornelian law, passed about A.U.C. 685, that when a prætor, on his accession to office, had published any edict or general rule, he should be bound to keep to it during the whole year of his office. After the adoption of this law, the prætors, though by no means bounded in the limits of their jurisdiction, were certainly tied down more strictly to the observance of the *litera scripta* of their edicts, and were not only obliged to submit to these edicts and to judge according to their provisions, but were responsible to the tribunes in the discharge of their functions. A prætor was not bound by the edicts of his predecessor; if he confirmed them, the edicts were called Vetera et Tralatitia; if he made new edicts, they were called Nova. On an occasion mentioned by Cicero ('De Offic.,' iii. 20) the prætors and tribunes of the Plebs united in drawing up a penal edict (edictum cum pœnâ et judicio) relative to the coinage. This instance will serve as an example of the extent to which the prætors under the republic exercised legislative power. Instead of confining themselves to rules for the regulation of the practice of the courts, they gradually assumed the power of repealing written law and making new laws, on the ground of correcting the error of the written laws whenever they seemed inapplicable from generality or other defect. But, as M. Schrader has shown, it was not by opposing the old laws,—objects of reverence to the Roman people,—but by bringing them into accordance with the necessities of the times and the changing manners of the people, that reforms in the law were intoduced by the Prætors. (See on this subject Abdy's 'Civil Procedure among the Romans,' chapter ii.; Hugo's 'History of the Roman Law;' and W. Smith's edition of Gibbon's 'Decline and Fall,' vol. v., p. 266.) From the decisions of the prætors arose a large body of law, whoh was known by the name of Jus Honorarium or Prætorium (Papinian. 'Dig.' i., tit. 1, 7), as distinguished from the Jus Civile, and may to a certain extent be considered as corresponding to the English courts of equity.

Under the early emperors the magistrates published edicts, but Hadrian commissioned Salvius Julianus (A.D. 132) to make a digest of all the best decisions, which were collected in a small volume called the Edictum Perpetuum, and ratified by a Senatus Consultum. From that time the power of making edicts was taken from the magistrates, and the legislative power was vested in the emperors. ('Cod.' i. tit. 17.) [Constitution, Roman.]

EDUCATION. [Schools.]

EDULCORATION. The operation of washing a finely divided solid with water, or other liquid, in which the solid is nearly or quite insoluble. It is chiefly employed in chemical analysis to separate soluble matters from insoluble precipitates. [Chemical Analysis.]

EFFENDI is a Turkish word, which signifies "Master, Monsieur," and is subjoined as a title of respect to the names of persons, especially to those of learned men and ecclesiastics; for example, *Omar Effendi*, *Ahmed Effendi*, in the same manner in which *Agha* is placed after the names of military and court officers, and is nearly equivalent to "Sir." The word Effendi occurs also as part of some titles of particular officers, as *Reis Effendi*, the former title of the principal secretary of state, and prime minister of the Ottoman empire, which was properly an abbreviation of *Reis-al-Kottâb*, that is, "the head or chief of secretaries or writers."

EFFERVESCENCE. The escape of bubbles of gas from a liquid. The phenomenon is seen when marble or chalk is dropped into vinegar, or when the cork of a soda-water or champagne bottle is removed.

EFFLORESCENCE (from *effloresco*, to blow as a flower). A term applied to the formation of small crystals on the surface of bodies, in consequence of the abstraction of moisture from them by the atmosphere. Thus carbonate of soda and sulphate of soda, when exposed to the air, part with their water of crystallisation, and crumble down, or *effloresce*, to a white powder. Other salts on the contrary, such as carbonate of potash and chloride of calcium, absorb moisture from the air and become damp, or even liquefy in the water so absorbed. This is called *deliquescence* (from *deliqueo*, to melt), and the salts are called *deliquescent*, as in the former case they are termed *efflorescent*.

EFFUSION. A term nearly related to DIFFUSION, and has reference to the velocities with which different gases pass through the same small aperture into a vacuum. These velocities are stated by Professor Graham ('Phil. Trans.' 1846) to be inversely as the square roots of the densities of the gases. The lightest gas enters the most rapidly, and any change in the density of the gas has but little influence on the rate of effusion, the volume effused in a given time being nearly uniform. The same law also applies to liquids in passing through an aperture in a thin plate. In the case of gases, Graham made use of an aperture of about $\frac{1}{500}$th of an inch in diameter. In the following table the numbers in the third column represent the rates of effusion of different gases obtained experimentally, and it will be seen that they coincide within the limits of experimental errors, with the relative rates of diffusion of the respective gases.

Gases.	Velocity of Diffusion.	Rate of Effusion.
Hydrogen	3·83	3·613
Light carburetted hydrogen	1·344	1·322
Carbonic oxide	1·0149	1·0123
Nitrogen	1·0143	1·0164
Olefiant gas	1·0191	1·0128
Oxygen	0·9487	0·950
Protoxide of nitrogen	0·82	0.834
Carbonic acid	0·812	0·821

[TRANSPIRATION.]

EGG, WHITE OF. [ALBUMEN.]

EGG TRADE. Apart from the interest belonging to eggs in connection with natural history, there is much that is remarkable in their relation to commerce and manufactures. The egg trade is now one of great magnitude. What the number of English eggs produced and consumed, either as food or in manufactures, may be, it is impossible even to guess; for there are no returns which can apply to this subject; but of foreign eggs we find that there have been imported the following quantities in recent years:—

1844	67,000,000
1847	77,000,000
1850	106,000,000
1853	123,000,000
1856	117,000,000
1858	135,000,000

These are principally obtained from France. The quantity imported in 1858 had a declared value of about 300,000*l*.

Eggs are largely employed in the leather manufacture, in the conversion of kid skins into leather for gloves and shoes. In one process of the manufacture, yolk of egg is mixed with alum, salt, and flour in a barrel, and the skins are agitated with this mixture for some time. Much of the softness of good kid leather is due to this use of egg-yolk. There is one leather-factory in Bermondsey where from 60,000 to 80,000 eggs are used for this purpose every year; they are imported from France in the spring, and are kept good throughout the year in lime-water.

Mr. Cooley makes the following observations on the preservation of eggs:—"Eggs may be preserved for any length of time by excluding them from the air; one of the cleanest and easiest methods of doing this is to pack them with the small ends downwards, in clean dry salt, in barrels or tubs, and to place them in a cool and dry situation. We have eaten eggs thus prepared that were more than twelvemonths old, and that had been for some months on shipboard, in a tropical climate, and which yet retained all the peculiar sweetness of new-laid eggs. With a like intention, eggs are placed in vessels containing milk of lime, or strong brine, or are rubbed over with butter, lard, or gum-water; all of which act by excluding the air. Eggs for keeping should never be laid on their sides; and when kept in the air, should be occasionally turned to prevent the yolk attaching itself to the side, instead of floating in the albumen. Some persons place the eggs in a netting, or on a sieve or colander, and immerse them for an instant in a caldron of boiling water, before packing them away. The practice of packing eggs in damp straw, or anything else that can convey a flavour, should be carefully avoided; the shells of eggs are porous, and readily admit the passage of gaseous substances, especially of fetid odours. It is from inattention to this point that a large portion of the eggs imported from the coast of France have a less delicate flavour than those of our poultry-yards. Damp dropped straw, as well as most other organic substances exposed to warmth and moisture, readily ferment or putrify; and during fermentation, a considerable increase of temperature takes place, as any one may readily perceive by examining the common hotbeds in our gardens, which are merely masses of organic matter in a state of decomposition. Eggs, as long as they retain the embryo of the future chick in a vital state, possess in themselves a certain degree of warmth, which tends materially to promote the decomposition of the substances they are packed in, particularly in the presence of moisture." In reference to the preservation of eggs, it may be stated that Mr. Jayne has patented a liquid for this purpose; consisting of two or three pounds of salt mixed with half a pound of cream of tartar, and dissolved in water to a brine strong enough just to float an egg. This liquid, it is stated, will preserve eggs fresh as long as two years; but Mr. Cooley is of opinion, that simple milk of lime will answer quite as well.

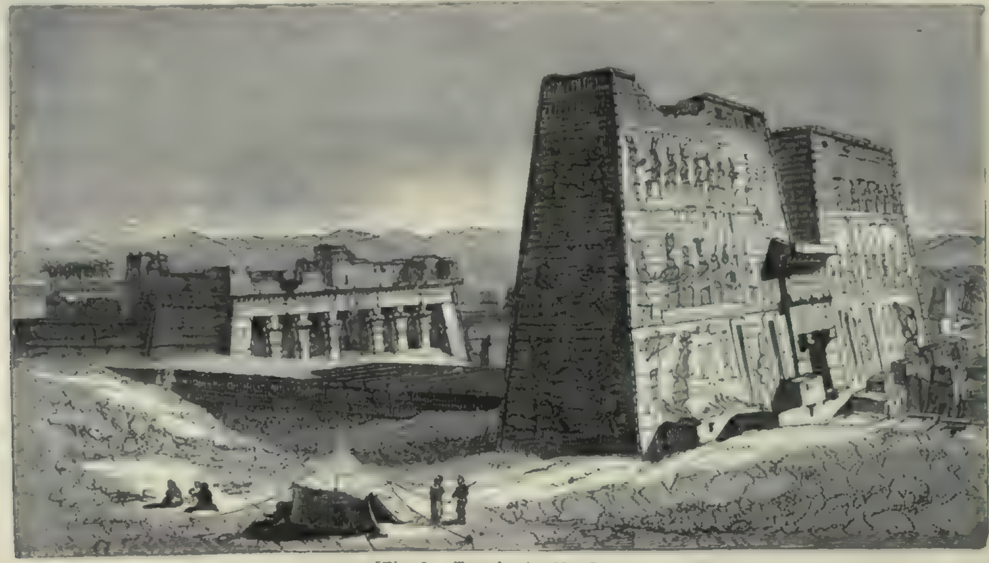
It affords a curious exemplification of the large scale on which the consumption of apparently trifling articles is now conducted, that in July, 1859, a suit in equity was tried between the inventors of two *egg-beating* machines. A patentee of a method of beating up the whites of eggs complained of another machine-maker for infringing his patent. The offender admitted the use, but denied the validity of the patent; and he brought forward proof that the inventors of two previously-patented churns, had anticipated all, or nearly all, that was really essential in the egg-beating machine.

EGYPTIAN ARCHITECTURE. The architecture of almost every civilised people can be traced to that of an earlier people or country, of which it is an adaptation or development. The architecture of Egypt is, however, an exception. It is the oldest architecture of which any examples remain, or of which we have any record; and it differs from all other architecture in its distinctive characteristics. In magnitude, solidity, and magnificence, it far surpasses that of every other country; but in unity of plan, grace of proportion, and æsthetic feeling, it will not bear comparison with the architecture of Greece. The ancient Egyptians appear in truth to have been not merely deficient in æsthetic culture, but their mental and national peculiarities were adverse to its reception. Further, they were controlled in all artistic work by immutable hierarchic rule, and free mental development was therefore impossible. The art of one age was, in a certain sense, that of all. If there was change, it was due to a change of dynasty, and therefore to a foreign influence.

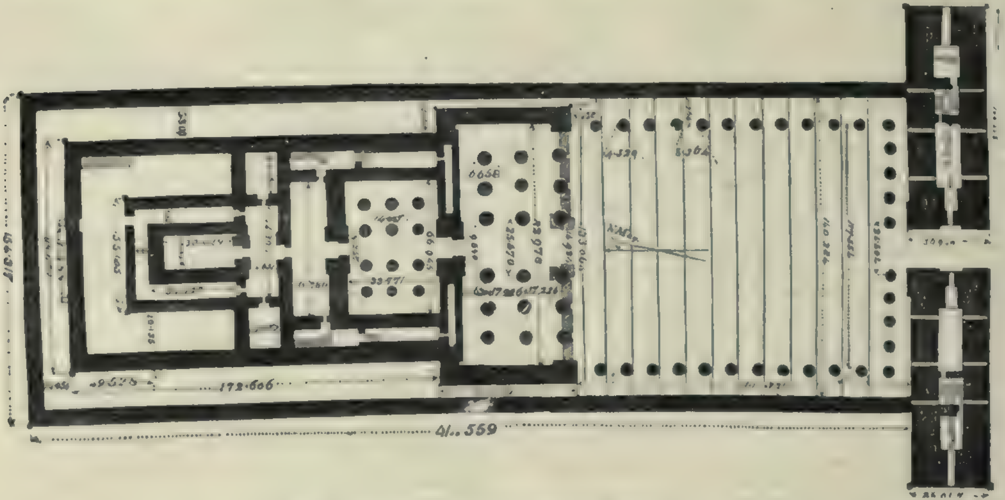
Were we to treat Egyptian architecture chronologically, we might divide it into the architecture of Lower, Middle, and Upper Egypt, and of Nubia; but we could not so treat it without entering into a fulness and minuteness of detail which would be quite out of place in a general sketch like the present. Within the limits assigned to us it will be most convenient to describe broadly the several great classes of structures, and the chief architectural members.

The most ancient edifices of Egypt are the pyramids, those of Gizeh being the earliest. But these we shall do little more than mention here, because, interesting as they are in themselves, they are structures of so very peculiar and distinct a nature as to have but little connection with the architecture of the country in general; being, when considered with reference to it, little more than uniform and simple though enormous masses. They are, in fact, greatly more important in an historical and archæological point of view than in one purely historical. Their shape is so familiar to every one that it requires no description, but may be defined as square in plan and triangular in section, its four sides being as many triangles united so as to terminate in a point; and as the height is much less than the width of the base, each side constitutes nearly an equilateral triangle. The extraordinary height and magnitude of these vast erections are combined with imperishable stability and solidity, the whole being nearly one entire mass of the hardest materials, for the inner galleries and chambers form but mere veins and cavities compared with the entire mass. For a description of them we refer to the article PYRAMIDS. For the same reason that we do not stay to describe the pyramids here, we may leave to a separate article those no less characteristic Egyptian monuments, the lofty four-sided monolithic shafts known to us as obelisks. [OBELISKS.]

The oldest really architectural Egyptian buildings are the great temples, or temple-palaces like that of Karnak; but as this enormous edifice was really an aggregation of buildings, the growth of ages, of which the nucleus appears to have been the sanctuary, built by Osertesen, the great king of the 12th dynasty, whilst the great court in front only dates from the 22nd dynasty, a clearer notion may be conveyed of the plan and character of an Egyptian temple by examining one of simpler form, though of later date. We select, therefore, as our example the temple at Edfou, or Apollinopolis Magna, erected under the Ptolemies, one of the largest and much the most complete of any in Egypt. Its dimensions are given on the ground plan. This it will at once be seen from the plan, was far more varied and complex than the plan adhered to by the Greeks, which, consisted merely of a cella, either surrounded entirely with columns, or with columns only in front, or at both ends. Here, on the contrary, the temple is placed within an enclosure, which forms also a court in front of it, surrounded on three sides by colonnades; and the entrance to this court was through a colossal doorway, or propylon, placed between two



[Fig. 1.—Temple at Edfou.]

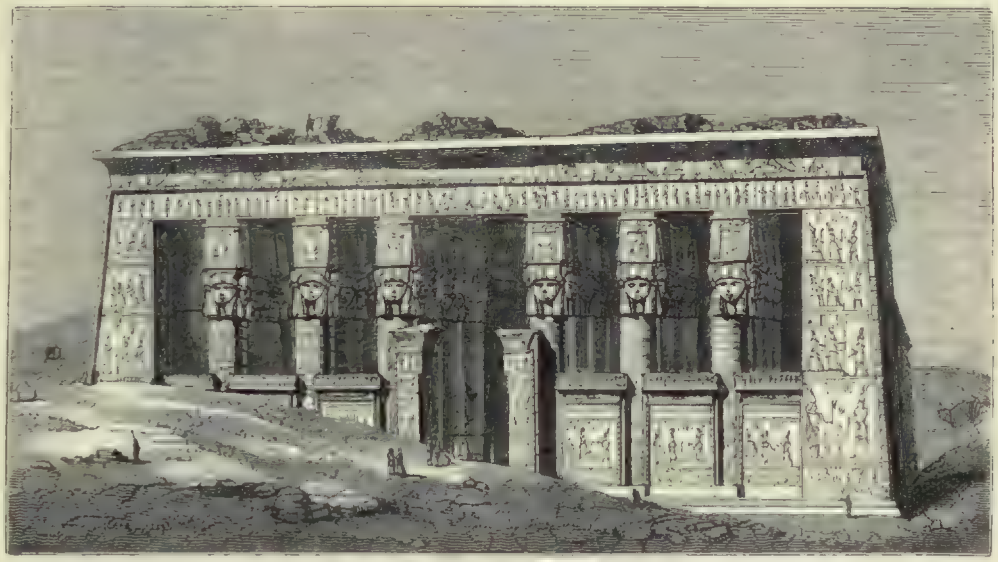


[Fig. 2.—Ground Plan of the Temple at Edfou.]

vast pyramidal towers, or as they are sometimes called pylons, covered with colossal figures in sculpture. These vast masses of structure, of which a much clearer notion will be formed from the cuts (*figs.* 1 and 2) than from a description, rose considerably higher than the temple itself. They are each 104 feet wide at the base, and diminish gradually to 84 feet at the summit, which is 114 feet high, and they were crowned by the usual cornice; they had likewise the torus moulding running up their angles, and are fine examples of their class. Other conspicuous objects frequently accompanying these propylæa, were lofty obelisks, as was the case at Luxor, where there still exist one in front of each tower. These towers may almost be said to be solid, for although they contained chambers and staircases, such spaces amounted to little more than voids left in the mass. Between these towers is the door, which leads into a spacious court, having a colonnade carried along three of its sides. Within the court the colonnades were pycnostyle, or a diameter and a half apart, which seems to have been the usual mode of intercolumniation adopted by the Egyptians, the columns being seldom more than a diameter and a half from each other, except in the centre of a portico, where there was generally a doorway between the columns, the lower part of the other intercolumns being walled up, as described above, and as shown in the view of Denderah (*fig.* 3). The floor of this enclosure (now filled with rubbish and wretched buildings), rises by gradual steps (as shown by lines in the plan), to the portico or pronaos, which answers to the great hypostyle hall of Karnak, and other older temples. This pronaos is narrower, as well as smaller than the first hall, passages being cut off at its ends by exceedingly thick partition walls. It consists of eighteen massive pillars, six in a row, the intercolumniation, which forms the doorway, being as usual the greatest. Of the front pillars the intercolumniations are walled up to more than half the height. From this we pass into a still narrower and smaller hall which has three rows of four columns each, so disposed as to occupy the whole area, leaving merely narrow aisles in every direction between them—a mode peculiar to Egyptian architecture, occasioned by the necessity for employing such thickly-set columns to prop the massive beams and slabs of stone composing the ceiling; and hence such apartments have obtained the name of *hypostyle* halls. These pillars have quadrilateral Isis-headed capitals of the kind described below. To this hypostyle succeed two chambers, the farther one having smaller lateral rooms attached to it, which, it is conjectured, were appropriated to the use of the priests; and facing its entrance was that leading into the *sekos*, cella, or shrine containing the figure of the deity. Whilst all the preceding vestibules and chambers are placed transversely to the longitudinal direction of the building, the last and innermost apartment is parallel to that direction, and in continuation of the line of approach; the reason for which is obvious enough, it being almost indispensably requisite that the statue of the divinity should be at one end, and directly facing the entrance. In all probability likewise the object aimed at in disposing the rest as we perceive it to be, was twofold; first, for the sake of having a great number of apartments to be crossed before the sanctuary was reached and thus rendering it more difficult of access and more mysterious; and secondly, for the sake of contrast, the other divisions of the plan being intended to be merely passed through, but this, on the contrary, being the termination of the whole. If we keep this in view, and the peculiar nature of the worship to which these temples were dedicated, the arrangement must be allowed to be appropriate, notwithstanding that under different circumstances it might be objected to as constituting a very strong anti-climax since every portion of it successively diminishes, the last of the sacred chambers being, as the plan shows, hardly equal to the space forming the great doorway between the two towers. Yet what is thus an anti-climax, if we have regard to dimensions alone, became a perfect climax that must have made a powerful impression on those who were allowed to penetrate into the *adytum*—the most sacred part of the fane—the presence chamber, as it were, of the presiding divinity, where the sanctity of the whole precinct was concentrated in a focus, and to which the magnificence and colossal grandeur of all the rest served merely as preparation and prelude.

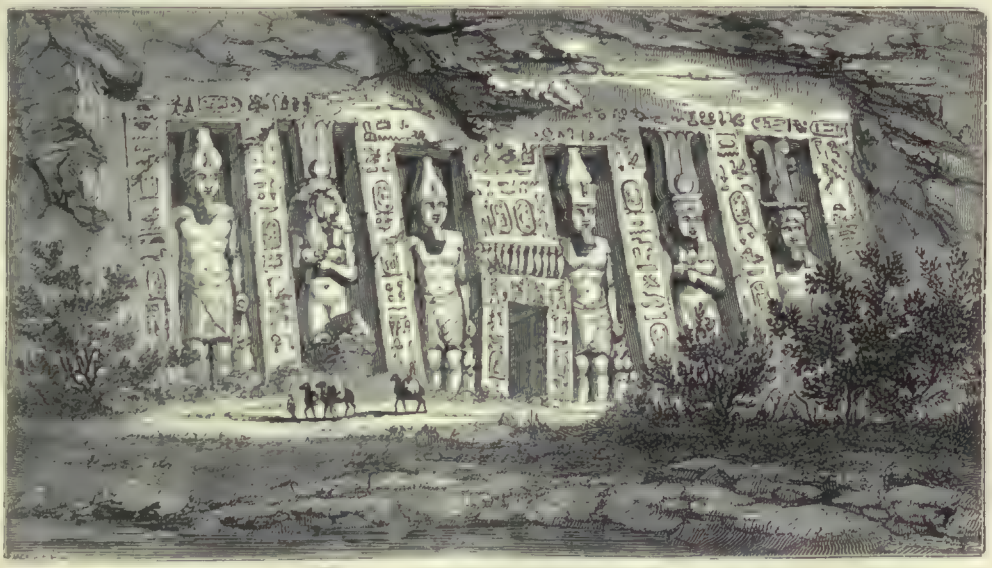
Such was the general disposition and distribution of an Egyptian temple. But, as was said above, in the older temples the hypostyle hall is a much larger and more important feature. That of the great temple of Karnak is 338 feet by 170 in extent, and has 134 columns disposed in nine parallel rows one way and sixteen the other. The hall consequently has the appearance of a grove of pillars; and their being so numerous and set so close together would have been no small inconvenience, had they not been of such prodigious bulk. But the smaller pillars of this hall are 9 and the larger 11 feet in diameter, and the intercolumniations are consequently equal to 13½ and 16½ feet. The central pillars are 70 feet high to the under side of the architrave. The area of this vast hall is 57,629 square feet; or with its two pylons, upwards of 80,000 feet—an area, as has been pointed out, greater than that of Cologne Cathedral, the largest of the Gothic cathedrals of Northern Europe, whilst four such churches as that of St. Martin's-in-the-Fields, London, would stand side by side within the hall without occupying its entire area. The effect of this vast grove of columns is spoken of by all who have seen it, as being surpassingly grand. The length of the entire building is upwards of 1200 feet; its breadth varies from 321 to 360 feet. It has twelve principal approaches, each of which has lofty doorways placed between enormous pylons, and before them have stood colossal statues, whilst avenues of sphinxes lead from them in various directions, one being continued the whole way across the plain to the temple at Luxor.

The engraving of the front of the great temple of Denderah (*fig.* 3), the most perfect of the existing monuments of Egypt, will serve to show the character of Egyptian architecture at a somewhat later date than that of the temple at Edfou. The temple, which is of vast extent, is enclosed within a square wall, the side of which is 1000 feet, and which is in parts 35 feet high and 15 feet thick. In general form this temple resembles that at Edfou, but it has no forecourt or propylon. This façade from its perfectness exhibits very distinctly the sloping profile of the walls, the peculiar entablature, and the hieroglyphic carvings, all of which are so characteristic of Egyptian architecture, as well as a remarkable form of capital. Later temples show more irregularity of plan.



[Fig. 3.—Front of the Temple at Denderah.]

In Upper Egypt and Nubia occur temples hewn out of the solid rock; but, like all excavations, they are copies of structural temples. The most remarkable is the great rock-temple of Ipsambul, or Abousambul, constructed by Rameses III. It has two faces formed out of the sandstone rock, each cut to resemble the front of a temple, while the temple itself penetrates 180 feet into the mountain. The front of the temple is nearly 100 feet high and 117 feet wide, and is adorned with four enormous colossi each 70 feet high, which produce a wonderfully impressive effect. The interior is in general plan like that of the structural temples; the first apartment is a pronaos 57 feet long and 52 feet wide, supported by two rows of large square caryatide pillars, in a line with the door of the sakos; beyond this is a smaller hall, supported by four columns; the sakos, or sanctuary, is 23 feet long by 12 feet wide, with a pedestal in the centre, and at the end four colossal seated figures. With the side or priests' rooms, there are in all fourteen different chambers. A smaller rock-cut temple at Abou-sambul is greatly inferior in design, but has a richly carved front 90 feet long, in which are six colossal figures hewn out of



[Fig. 4.—Smaller Temple at Abou-Sambul.]

the rock. (*Fig.* 4.) The extreme end of this temple reaches 76 feet into the rock.

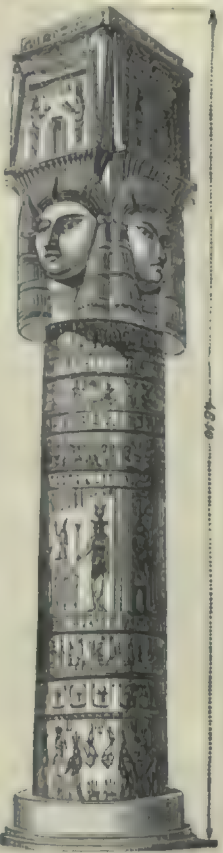
Having thus described the general plan and arrangements of the temples as the chief and most characteristic class of Egyptian buildings, we proceed to notice some of the principal elementary parts of which they are composed.

The diversity observable in Egyptian columns is so great that it is impossible to specify here all their varieties, which can be understood only by studying the engravings in the large works devoted to Egyptian antiquities. Nor can they be reduced to any system, there being no peculiar form of capital or other distinct characteristic attaching to any particular type of column; nor anything in regard to proportion whereby they can be classified. There can be little doubt that the oldest and simplest form of Egyptian column was that of a plain square pier. From these, octangular, polygonal, and eventually cylindrical columns, were produced by the simple process of cutting off the angles. As a general rule, Egyptian columns, of whatever kind, were vertical in profile, thus contrasting in a marked manner with the sloping profile of the building. It must not be understood, however, that the shafts are either invariably or perfectly cylindrical, but that such was their general form. There is sometimes a slight difference between the upper and lower diameter; or else the shaft is cinctured at intervals by bands consisting of three or more rings encircling it, and thereby increasing the diameter in those parts. In addition to this species of ornament, the shaft was variously decorated in other respects, the spaces between the bands being sometimes sculptured with hieroglyphics; at others, reeded, that is, its surface was divided into a series of upright mouldings, or staves, so as to have the appearance of a bundle of smaller pillars bound together, and which, with the encircling of the shaft with ring mouldings, has suggested the idea of their being an imitation of reeds, or thin palm stems, banded together. The kind of striating, or striping, just described, is the reverse of that practised in the Doric and other Grecian orders, since in the latter it was produced by concave channels, or flutings, but in this by convex surfaces. In the rock-cut tombs of Nubia, however, true-fluted proto-Doric columns occur, the only character of the Greek Doric absent being the echinus moulding under the abacus: a characteristic example is that of the tomb at Beni-Hassan. Under COLUMN (col. 44) is a cut of an Egyptian column, now in the British Museum, in which are shown the cartouches of hieroglyphics spoken of above.

Egyptian columns have rarely any distinct base, seldom more than a circular plinth; but they have frequently an ornamental footing, which differs however from a base in being contracted instead of expanded below. It may be described as shaped like the calyx of a flower, the resemblance to which is increased by its being sculptured into some forms of foliage, so that the shaft appears to be set in and rise out of a plant. Of this description are the bases of the columns of the temple at Latopolis or Esné. By some this has been insisted upon as a defect and as indicative of weakness: consequently, contrary to that law of architecture which prescribes that there should be apparent as well as real strength, more especially where the expression of solidity is naturally looked for. Still it may not unreasonably be urged that, as in all such cases, the judgment comes to the aid of and corrects the eye: what is known to be strong cannot fairly be said to appear weak; and the solidity of columns which have stood the test of some thousands of years cannot possibly be called in question. It may ndeed be argued that the excess of strength which they gave their structures, and the prodigious solidity and durability of the materials employed, allowed the architects of Egypt to contract the diameter of their columns below, without rendering them at all weak.

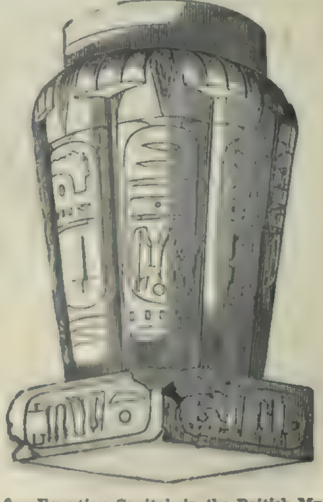
The most usual form adopted for capitals was that of the cup of the papyrus or the calyx of the lotus, but occasionally of some other flowers, with a rim bending downwards, which was sometimes quite circular, at others jagged, the circumference being divided into a number of convex curves, forming so many distinct petals. The six specimens given in the article COLUMN (col. 46) exhibit two of the latter and three of the first-mentioned variety of the bell-shaped capital.

From these it will be seen what variety prevailed in the decorative details, some being cut into distinct leaves, either convex or concave, others embellished with sculpture representing branches and flowers. It will also be perceived that, in their general mass, the capitals of this class, far from having anything in common with that of the Grecian Doric, bear a general similarity to that of the Corinthian order, though both the foliage and its arrangement are of a different character. Yet there is not now much doubt that the Greek Corinthian order may, like the Doric, be traced to an Egyptian source. But there exists an exceedingly wide distinction between the Egyptian and every variety of either Grecian or Roman capitals; namely, in the abacus being a mere square plinth, considerably smaller than the capital. The Egyptian abacus is anything but ornamental in itself, and would be a defect, were it not that in the buildings it can hardly be seen, owing to its smallness and the projection of the rim of the capital; consequently, unless it happened to be very deep, it serves chiefly to detach the capital from the architrave, and prevent that heaviness of appearance which would otherwise be occasioned. The first figure among the specimens given under COLUMN shows an example of what may be termed the double capital, peculiar to Egyptian architecture; for above the usual shaped capital is a square member, sculptured on each of its sides with an Isis' head; and on this again is placed a second square member, so that instead of a double this may be termed a triple capital. The columns of the temple at Denderah (*fig.* 5) offer another instance of the double capital in some respects similar to, in others greatly differing from the preceding. Here the lower capital consists of four Isis' faces, disposed so as to form a square, larger than the shaft, the folds of the head-dress hanging down and projecting beyond it: above each face is a kind of fluted abacus, and above is a square member. The shaft also varies considerably from those shown in the preceding examples; for instead of being striated vertically and banded horizontally, this is covered with hieroglyphics disposed in series of rings. Another remarkable circumstance is the great height of the whole capital, it being not less than two-fifths of the shaft.



[Fig. 5.—Column from Denderah.]

There is another species of capital of very frequent occurrence, which is distinct from either of the above two classes; and although its form may at first sight be considered uncouth, it is well calculated for effect. After sweeping out from the shaft, instead of continuing to expand as it proceeds upwards, it slopes back so as to diminish until it



[Fig. 6.—Egyptian Capital, in the British Museum.]

is contracted again to the diameter of the shaft itself. The decoration consists in its being subdivided into eight lesser shafts, inscribed with hieroglyphics, as are likewise the faces of the abacus, which member here becomes very pronounced, and occasions a picturesque play of light and shade. Capitals of this kind, as well as other varieties, occur at Luxor. In their proportions, Egyptian columns vary no less than in other particulars, their height amounting in some instances to no more than three diameters, in others extending to eight or upwards. Yet such difference is not attended by any regularly corresponding one, either as regards the column itself or the parts connected with it. Further, it is by no means unusual to meet with square pillars or *tetrapleurons*, with either a statue or a caryatide figure standing before but distinct from it. One of these from Medinet Abou is figured under ATLANTES (vol. i. 689). There are also terminal caryatide columns at Karnak.

The Egyptian entablature is so far from displaying anything like the same variety as the columns, that it is nearly uniformly the same in buildings which differ very much from each other in regard to their columns. Unlike that of the Greeks, it consists of only two divisions, the epistylium or architrave, and the cornice; the height of both being generally one-third of that of the columns. More frequently than not the epistylium was enriched with sculpture in hieroglyphics, which circumstance alone constitutes a great difference between the practice of the Egyptians and that of the Greeks. Another singularity is, that the epistylium was included within the convex moulding or *torus* carried up at the angles of the building, and then returned horizontally along the front, owing to which the architrave itself (epistylium) appears to be returned downwards, like that of a door or window. This will be at once understood by referring to the view of Denderah (*fig.* 3), by which it will also be seen that the cornice consists of little more than a deep cove enriched with sculpture,—a form peculiarly adapted for effect in a climate like that of Egypt, as it not only casts a bold shadow but receives a strong reflected light.

With the cornice the building terminated, for the roof being a flat terrace, there was no indication of roof; consequently Egyptian architecture is entirely destitute of what are such expressive and highly ornamental features in that of Greece, namely, the pediment, antifixæ, and ridge tiles. By way of indemnity for its deficiency in this respect, and the sameness arising from it, greater latitude was allowed to it in others. Not only was there far greater diversity in the forms and ornaments of columns, which do not appear to have been subject to any regulations beyond these prescribed either by symbolic allusions or by national taste; but columns of very different character appear in the same edifice, and even capitals of different design in the same range of columns. Another thing peculiar to Egyptian buildings is the frequent use in the external porticoes of temples of intercolumnar walls, or screens, that is, walls built between the columns and carried up half their height; thereby giving to the open part of the intercolumns above them somewhat the appearance of windows. For an example, we again refer to the view of Denderah, in which instance these walls are brought forward so as to encase the shafts of the columns between them, and fling a shadow upon them. Like every other part of the front in the same edifice, these walls are decorated with sculpture and hieroglyphics; for the Egyptians were exceeding lavish of that species of embellishment, not confining it to particular situations, as did the Greeks, namely, to the pediment, frieze, and inner frieze behind the columns, along the walls of the cella, but extending it over the entire surface, in compartments forming tier above tier. These architectural sculptures were generally in very low relief, and some of them also occasionally in intaglio, or hollowed into the surface instead of projecting from it. There are even instances of a combination of both modes, the figures being outlined by a groove or incision, so as to give them greater apparent relief; a mode that has been denominated by some intaglio-rilevato. In addition to this species of enrichment must be added that of colours and gilding: the whole of the sculpture which covered the walls, the capitals of the columns, and much, if not the whole, of the columns themselves, and the beams and ceilings, were brilliantly coloured. The colours employed in all parts of Egypt were, according to Sir Gardner Wilkinson ('Anc. Egyptians,' iii. 301), red, green, and blue; and when black was introduced yellow was added to harmonise it. Fairly to estimate the effect of this, as it might otherwise seem, excessive polychromatic decoration, the extreme brilliancy of the Egyptian climate must be constantly borne in mind.

In Egyptian architecture, even more than in Grecian, doorways are conspicuous and important features, where they occur as distinct parts of the design in the form of towers; sometimes standing quite insulated after the manner of arches or gateways; yet more usually placed between and connecting two pyramidal pylons that rise to a great elevation above the propylon itself; consequently such entrance is both lower and narrower than the parts attached to it. In its general form the propylon or gateway resembled the temple itself, yet with this difference, that the proportions of the propylon are lofty and narrow; those of the temple wide and low, and its opening filled with columns supporting the lintel or epistylium. Their similarity in all other respects is obvious enough, owing to the epistylium of the portico being returned and carried downwards just as the lintel of the door is in order to form its jambs. The outer angles are similarly inclined in both cases, and ornamented with the same torus moulding on their edge. It should be understood, however, that the jambs of the doorway were for the most part, not vertical next the opening, but sloped like the external angles, so that the aperture was narrower at the top than at bottom, which form seems to have been copied by the Greeks in that of their doors and windows. The lintel and cornice above it were also proportionably much deeper than the epistylium and corresponding member, over columns, in order to produce sufficient mass; otherwise the effect would have been both unarchitectural and disagreeable, too much like that of the mere framing of a door, standing, although not quite insulated, yet distinct from the rest of the composition. Some idea may be given of the imposing magnitude of such doorways or propyla, by stating that the one at Edfou measures 74 feet to its summit, and 51 to that of the aperture, which gives a depth of 23 feet, or nearly one-third of the whole height, for the lintel and cornice.

The magnificence of these propylea was greatly enhanced by colossal statues or obelisks—in some instances both—placed on either side of the entrance. Besides which there were sometimes two or even more propylea and courts preceding the temple, which were in their turn preceded by avenues of gigantic sphinxes or crio-sphinxes (that is, sphinxes with rams' heads). There are, likewise, instances of avenues of columns crossing the courts in a line from the entrance. The remains at Luxor furnish an example of the kind, where, after the first court (which has a double peristyle), there is a second with a double range of columns extending down it, that are 11½ feet in diameter and 56 high, and beyond this was a third court, flanked by colonnades, consisting of double rows of pillars.

Of the domestic architecture of the Egyptians there are but few vestiges left. The so-called temple-palaces have but little of the character of even a royal residence. At Medinet Abou, in Western Thebes, enclosed within an extensive brick-wall are a temple, or building that has been called a palace, but appears to be also a temple, and a much smaller structure which is considered to have been a royal pavilion erected by Rameses II. All that remains of this last is a singularly picturesque structure two stories high, though it was originally, no doubt, a three-story building, with three rooms with long-connecting corridors on each floor. The chief front is sculptured with colossal figures, has wide window openings, and is crowned with the usual cornice.

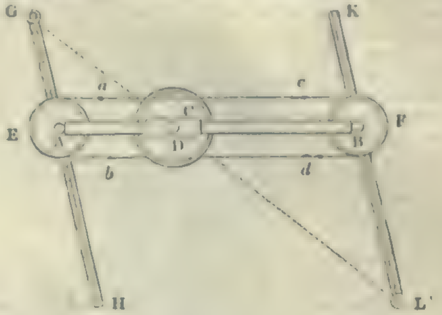
Of the mansions of the higher and affluent classes, pretty nearly all that is known is derived from Egyptian paintings. These have been most thoroughly examined by Sir J. G. Wilkinson, and the little it it seems necessary to add on this subject we borrow from him. The private houses of the Egyptians, and indeed all buildings, except temples and temple-palaces, appear to have been built of crude brick. The town-houses of wealthy citizens frequently covered a considerable space, were seldom more than three stories high, and presented to the street either the sides of the house itself, or the walls of the court attached to it. Sir Gardner Wilkinson ('Ancient Egyptians,' vol. ii. 101–4), thus describes these buildings: "Their plans were regular, the rooms being usually arranged round an open area, or on either side of a long passage to which an entrance-court led from the street. The court was an empty space, considerably larger than the Roman impluvium, probably paved with stone, or containing a few trees, a small tank, or a fountain in its centre; and sometimes, though rarely, a flight of steps led to the main entrance from without. A court was frequently common to several houses: and again, some of the large mansions stood detached, and had the advantage of several doors of entrance, on two or three different sides. They had a portico, or porch, before the front door (janua), supported on two columns, below whose capitals were attached ribands or banners: the name of the person who lived there being occasionally painted within, on the lintel, or imposts of the door; and sometimes the portico consisted of a double row of columns, between which stood colossal statues of the king. A line of trees ran parallel with the front of the house; and, to prevent injuries from cattle or from any accident, the stems were surrounded by a low wall, pierced with square holes to admit the air. The height of the portico was about twelve or fifteen feet, just exceeding that of the cornice of the door, which was only raised by its threshold above the level of the ground. On either side of the main entrance was a smaller door, which stood at an equal distance between it and the side wall, and was probably intended for the servants, and those who came on business. On entering by the porch, you passed into an open court (*aula*, or hall), containing a *mandara*, or receiving-room, for visitors. This building, supported by columns, decorated with banners, was closed only at the lower part by intercolumnar panels, over which a stream of cool air was admitted, and protection from the rays of the sun was secured by an awning that covered it. On the opposite side of the court was another door, the approach to the *mandara* from the interior; and the master of the house, on the announcement of a stranger, came in that way to receive him. Three doors led from this court to another of larger dimensions, which was ornamented with avenues of trees, and communicated on the right and left with the interior of the house; and this, like most of the large courts, had a back entrance (*posticum*), through a central and lateral gateway. The arrangements of the interior was much the same on either side of the court: six, or more chambers, whose doors faced those of the opposite set, opening on a corridor supported by columns on the right and left of an area, which was shaded by a double row of trees. At the upper end of one of these areas was a sitting-room which faced the door leading to the great court; and over this and the other chambers were the apartments of the upper story. Here were also two small gateways looking upon the street." The floors were made of stone, or cement; the roofs were supported by rafters of the date-tree arranged close together, and sometimes vaulted, being built like the rest of the house of crude brick. On the top of the house was a terrace, covered by a roof supported by columns. The porticoes, walls, ceilings, &c., were all elaborately painted in patterns. The country-houses of the nobles were very commodious mansions, with spacious gardens, fish-ponds, farmhouses, granaries, &c., attached. "Some large mansions appear to have been ornamented with propyla and obelisks, like the temples themselves; it is even possible that part of the building may have been consecrated to religious purposes, as the chapels of other countries, since we find a priest engaged in presenting offerings at the door of the inner chambers; and, indeed, but from the presence of the women, the form of the garden, and the style of the porch, we should feel disposed to consider it a temple rather than a place of abode. The entrances of large villas were generally through folding-gates, standing between lofty towers, as in the propylæa of temples, with a small door at each side; and others had merely folding-gates with imposts surmounted by a cornice. A wall of circuit extended round the premises; but the courts of the house, the garden, the offices, and all the other parts of the villa, had each their separate enclosure. The walls were usually built of crude brick; and in damp places, or when within reach of the inundation, the lower part was strengthened by a basement of stone. They were sometimes ornamented with panels and grooved lines, generally stuccoed; and the summit was crowned either with Egyptian battlements, the usual cornice, a row of spikes in imitation of spear-heads, or with some fancy ornament." (Wilkinson, ii. 128.)

One other class of structures—the tombs—requires a word of notice since, besides possessing some points of architectural interest, it is from them that we derive by far the greater part of our knowledge of the arts and civilisation of ancient Egypt. Of these, the oldest and most important, if we omit the pyramids, are the tombs of the Theban kings, in the valley of Biban-el-Meluk, which are excavations in the solid rock, often of great extent. Many of them have a rich architectural entrance façade, and all have their interior walls covered with paintings and hieroglyphs of exceeding value from the information they afford respecting the manners, customs, and history of the people. Of these tombs, the most famous is that of Manepthah, who built the great hypostyle hall at Karnak, which extends in a sloping direction for about 350 feet into the mountain, and which terminates in a spacious chamber, in which stood the costly sarcophagus. Many of the later tombs are commonly of crude or unburnt brick. These tombs have a peculiar interest in connection with the history of architecture, as presenting unimpeachable evidence of the remote antiquity of the invention of the arch. A tomb at Thebes, which belongs, according to Wilkinson, to the reign of Amunoph I. (B.C. 1540) has a vaulted brick roof; and in a tomb at Sakkara of the time of Psamaticus II. (B.C. 600), whose name is engraven on it, occurs an arch of stone. But though these and other examples prove that the Egyptians were acquainted with the theory of the arch, they appear only to have employed it in pyramids, tombs, and underground structures.

EIDER DOWN. This beautiful substance is obtained from one species of the duck, called the eider duck, found extensively in the icy seas of the north. There are two kinds of eider down, the live and the dead. The live down consists of the exquisitely light feathers which the duck strips off from herself to keep her progeny warm in the eggs. Its lightness and elasticity are such that two or three pounds of it, squeezed into a ball which may be held in the hand, will swell out to such an extent as to fill a case large enough for the foot-covering of a bed. The quantity of down afforded by one duck during the whole period of laying is about a pound. The down-gatherers are obliged to be cautious not to carry their somewhat cruel robbery too far, or the ducks will not again return to the same spot. Any district in which the eider duck is willing to settle is regarded as a valuable property in Norway and Iceland, and the landowners do their best to encourage their settlement. The *dead* down is that which is taken from the dead duck; it is inferior to the live down. Eider down is used chiefly in connection with beds and bedding.

EIDOGRAPH, from the Greek words *εἶδος*, a form, and *γράφω*, to draw, is an instrument invented in the year 1821, by the late Professor Wallace of Edinburgh, and described in the 'Transactions of the Royal Society of Edinburgh,' vol. xiii. It is a species of pantograph, and, like the latter, it is used for the purpose of copying plans or other drawings on the same or on different scales.

A rod or beam A B of brass, 30 inches long and five-eighths of an inch square, and made hollow for the sake of being light, slides freely through a hollow rectangular socket C, whose length is 4½ inches; from the lower surface of this socket projects a steel pin of a conical form, and serving as an axis; the pin entering into a tube of a corresponding form which stands vertically on a cylindrical mass D of metal. The mass serves as a base for the whole instrument; and while the beam A B may slide horizontally in the socket C, it is capable of turning with the socket upon the vertical axis in the tube. Each end of the beam A B carries a short tube in a vertical position, and through this passes the conical axle of a wheel or pulley E or F, which is placed below the beam; these wheels are precisely equal in diameter, and are capable of turning freely on their centres in a horizontal plane.



The vertical edge of each of these wheels is grooved so as to receive a piece of very thin watch-spring *a* E *b*, C F *d*; and the ends *a* and *c*, *b* and *d* are connected by a steel wire; the pieces of watch-spring are made fast near E and F to the circumferences of the wheels, in order to prevent them from slipping on those circumferences; a small movement for the sake of adjustment only being allowed. Swivel screws at *c* and *d* serve to tighten or relax the band as may be necessary.

Under each of the wheels E, F, is fixed a rectangular socket similar to C, and in this slides, horizontally, a rectangular arm G H, K L, each of which is 27½ inches long: these arms, which turn with the wheels E and F, are adjusted by means of the screws at *c* and *d*, so as to be always parallel to one another. At L is fixed a tracing point, like that of a pantograph; and at G a pencil in a socket or tube; the tracer and pencil are to be always in a straight line, passing through the common axis of the mass D, and of the socket C. The pencil is made to press gently on the paper by weights, but it is capable of being raised from thence at pleasure by means of a lever, one end of which is connected with the socket which carries it, and to the other is attached a string which is to be pulled by the operator when necessary: this movement of the pencil carrier is facilitated by means of small friction rollers.

The beam A B is divided on its upper face in 100 or 1000 equal parts, and divisions equal to these are set on the upper face of each arm G H, K L. By these divisions the distances of A and B from the axis of D may have any given ratio to one another, and A G, B L may respectively be made equal to the last-mentioned distances. Thus, the isosceles triangles G A D, D B L will always be similar to one another; and the figure described by the movement of the pencil at G will be similar to the original figure over which the tracer at L may be made to pass. Consequently, a given plan or drawing may be enlarged or reduced in any required proportion.

Professor Wallace contrived an instrument which he called a 'Chorograph,' for describing on paper any triangle, having one side and all its angles given; also for constructing two similar triangles on two given straight lines, having the angles given. See 'Geometrical Theorems,' &c. By William Wallace, LL.D. Edinburgh, 1839.

EIGHTH (in music), the octave or eighth note of the diatonic scale. It is a perfect concord [CONCORD], and in harmony is accompanied by the 5th and 3rd; but being almost identical with the base note, it may form a part of any chord, or be omitted at discretion.

EISTEDDFOD, from *eistedd* to sit; a meeting or assembly. This term was more especially used as the name for the session of the bards and minstrels which was held in Wales for many centuries. [BARD.] Near the close of the last century some Welsh gentlemen determined to endeavour to establish bardic meetings. The experiment proved extremely popular, and ever since periodical meetings, to which the name of Eisteddfod has been given, have been held successively in the principal towns in Wales. The principal object of these modern eisteddfodau has been to encourage the study of the Welsh tongue, and to keep alive a national spirit; and with that view prizes are awarded to the best Welsh poet, the best player on the Welsh harp of national melodies, &c.

EJECTMENT is the name of an action at law, by which a party entitled to the immediate possession of lands or other corporeal hereditaments may recover that possession from the party wrongfully withholding it.

Since the disuse, and subsequent abolition, of real actions, it has become the only legal mode of trying the title to lands and tenements. The procedure in it was re-modelled, and is now regulated entirely by the Common Law Procedure Act of 1852.

The old remedy by ejectment, better known as *John Doe* v. *Richard Roe*, was founded almost entirely upon a succession of legal fictions, and it is therefore necessary to give a short account of its history and the proceedings under it.

Originally this action was brought by any person having a lease of lands, to repair an injury done him by dispossession; but gradually it became the means of indirectly bringing in question the title to the lands, which was thus collaterally tried with the supposed trespass. For this purpose it was necessary that the claimant should enter upon the lands in order to empower him to constitute a lessee for years who would be capable of receiving the injury of dispossession. A lease for years was therefore stated to have been made by the party claiming title to the plaintiff, who was a fictitious person, John Doe. It was also stated that the lessee, in consequence of the demise to him, entered into the premises, and that the defendant, who was also a fictitious person, Richard Roe, and called the *casual ejector*, entered thereupon and ousted the plaintiff, for which ouster the plaintiff brought his action.

A notice professing to be written by the casual ejector to the tenant in possession of the premises, advised him to appear in court at a certain time and defend his title; otherwise he, the casual ejector, would suffer judgment to be had against him, by which means the actual tenant would inevitably be turned out of possession.

The declaration, in the action, formally stated the *lease*, *entry*, and *ouster*, and it and the notice were then served upon the tenant in possession of the premises, who had thus an opportunity of defending his title. If he omitted to do so within a limited time, he was supposed to have no right; and upon judgment being obtained against the casual ejector, the real occupier was turned out of possession by the sheriff.

If the tenant applied to be made a defendant, he was allowed to appear upon condition that he entered into a rule of court to confess at the trial of the cause four of five requisites for the maintenance of the plaintiff's action—the lease of the lessor, the entry of the plaintiff, the ouster by the tenant himself, and the possession by the tenant. These requisites were wholly fictitious; and if the plaintiff should put the defendant to the proof of them, he would of course be nonsuited at the trial; but the stipulated confession of lease, entry, and ouster being made, the case then rested upon the merits of the title only, and the cause went to trial under the name of the fictitious lessee on the demise of the lessor, who was the person really claiming title against the defendant.

The lessor was bound to make out on the trial his title to the premises; and if he did so in a satisfactory manner, judgment was given for the nominal plaintiff, and a writ of possession went to the sheriff to deliver up the possession to him, under which process it was in fact delivered to the real claimant. If it appeared that the person claiming title had no right of entry, that is, no right to the immediate possession, he could not maintain his action.

The Common Law Procedure Act, 1852, has abolished the fictions above alluded to, by substituting for the declaration *Doe* v. *Roe* and the notice by *Roe* to the tenant in possession, a single writ, directed to the tenant in possession, in which the plaintiff asserts his right to the property described in it. If the tenant, or his landlord who is entitled to notice from the tenant, disputes the claimant's right, one or other must appear and defend the action, the appearance being construed to be a denial of the title of the claimant, on which the parties may proceed to trial. If the tenant or his landlord does not appear, the claimant obtains an ordinary judgment by default, on which the sheriff gives him possession.

A mortgagee may maintain an action of ejectment against the mortgagor to gain possession of the mortgaged premises without giving any notice, unless the mortgagor is protected by the covenant for quiet enjoyment until default. He may also eject the lessee, to whom the mortgagor has made a lease subsequent to the mortgage, without giving him notice to quite. Where the right of the tenant to retain the possession has ceased by effluxion of time, by a legal notice to quit, or by the commission of an act of forfeiture, a landlord may bring an ejectment against his tenant; and various other persons who have a right of entry in law upon the premises may take advantage of the same remedy.

The time within which an action of ejectment may now be brought is regulated by the 3 & 4 Will. IV. c. 27, which enacts that no person shall bring an action to recover any land or rent but within twenty years next after his right to bring such action, or that of the person through whom he claims, shall have first accrued. The third section fixes the time at which the right shall be deemed to have first accrued. (Blackstone's 'Commentaries,' Mr. Kerr's edit., vol. iii. p. 206.)

ELAENE. [NONYLENE.]

ELÆOPTENS. [ESSENTIAL OILS.]

ELAÏDIC ACID. [OLEIC ACID.]

ELAÏDINE, a fatty substance, of uncertain composition, produced by the action of nitrous acid upon certain oils, as olive and almond oil, &c. This substance is white, inodorous, insoluble in water, and fusible at 95° Fahr. It is soluble in ether, and in 200 times its weight of boiling alcohol; when treated with potash it saponifies, giving rise to glycerin, and a peculiar acid which has been called elaïdic acid. This acid is solid, fusible at 112° Fahr., and is partially distilled by exposure to a strong heat. [OLEIC ACID.]

ELAIÖDIC ACID. [RICINOLIC ACID.]

ELALDEHYD. When aldehyd is kept for some time in sealed tubes, it is converted into two polymeric bodies, *metaldehyd*, a hard crystalline inodorous solid, and *elaldehyd*, which is a liquid. [OTHYL, HYDRIDE OF.]

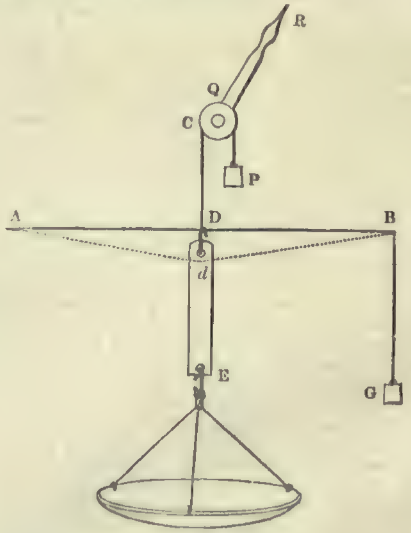
ELASTICITY. When the form of a body is affected by the pressure of another extraneous to it, the re-acting force by which it sustains or tends to remove that pressure is its elasticity. This energy of restitution is thus defined by D'Alembert:—"La force elastique est une propriété ou puissance des corps, au moyen de laquelle ils se rétablissent dans la figure et l'étendue, qu'une cause extérieure leur avait fait perdre." The term has been very loosely used in popular works, which, instead of furnishing an exact and general idea of this force, are, in general, limited to the phenomena exhibited by elastic solid bodies; and to this imperfect notion of elastic force we are to attribute the discrepancies of treatises, some of which used to represent water as perfectly inelastic, some (as the more modern treatises) as perfectly elastic. The cause of elasticity then belongs to the theory of molecularity, its effects in aggregate masses to mechanics.

The equilibrium of the *molecules* of solid bodies is almost completely dependent on their own mutual actions and quantity of heat. These forces determine certain mean places for the constituent particles, to which points of stable equilibrium they tend to return when removed a little from them by an external force. This removal may be such as to effect in the mass either compression or extension, inflexion, or torsion, and therefore their elastic force is capable of being exhibited in all these ways. It is demonstrated in fluids only by their compressibility, while in gases it acts as a predominant living force which would refuse any position of equilibrium to the constituent particles without external pressure, and is proportional to such pressure uniformly exercised.

When heat is applied to a solid elastic body, that is, when its temperature is raised, the particles seek a different position of equilibrium more remote from each other than before. But while this heat is much below that necessary for friction, or for destroying the fibrous formation of organized matter, the stability of the removable particles is but little affected, and experiment shows that there is scarcely any change of elasticity. In fluids the compressibility obtains a greater range, while in gases, where no countervailing force of attraction is sensible, the increase of temperature is accompanied by a proportional increase of elastic force.

Amongst bodies whose elasticity is very apparent, we may enumerate glass, ivory, caoutchouc, sponges, and fibrous substances, as beams, muscles, and artificial webs, some gums, steel, and all the gases and vapours. In gases and vapours its effects may be produced to any extent, but they are limited in solids by their softness and facility of fusion, as in wax, lead, &c.; by their absorption of moisture, as in clay, feathers, catgut, straw; or by their friability, as in glass, dry resins, and copper or iron which have been exposed to a stream of ammoniacal gas.

Suppose an elastic string, or lamina, to be fixed at one end, and at the other stretched by a force T, which will also represent its tension; if this force be increased by a small quantity t, an additional length l would be given to the string, or lamina; the whole tension now is $T + t$, and if we again add a force t, since the physical condition of the body is sensibly the same as before, the same length l will again be added, and generally the additional extension should be proportional to the additional tension: this law is, however, only approximative, for it is manifest that a force tending to produce either extension or contraction may be applied which would cause the body to break, and near these limits the law would vary considerably from simple proportionality. Let a horizontal elastic lamina A B be fixed by a screw at A, and having been stretched by a known weight G at B let it be screwed also at that point, when its tension will evidently be equal to the weight appended; let the beam D E of a balance F be sustained at D, the middle of A B through a drilled orifice d, and be attached to a string passing over the fixed pulley C, which string also sustains a weight P, which is an exact counterpoise to the weight of the scale and beam so that they may produce no deflection of themselves in A B; then if a small weight be put into the scale, the lamina A D B will be bent into the form A d B, with a deflection D d from its original



position, which may be estimated with greater accuracy by a hand Q R attached to the pulley. An extension A d B − A D B will thus be produced, as well as an increase of tension, which may then be compared by the common laws of statics; and the experiments show that as long as the added weights are small, "this *extension* is proportional to the increase of *tension*." This law is that expressed by Hooke: "*Ut tensio sic vis.*"

When a uniform elastic string is suspended vertically it will be stretched by its own weight. The tension varies from point to point, and is everywhere proportional to the portion of the string of which it supports the weight. If y be a portion of the stretched string corresponding to a portion x of the same unstretched, and $y + \triangle y$, $x + \triangle x$, another corresponding pair of portions greater than the former, and a the whole length of the string in its natural state, the extension $\triangle y - \triangle x$ of the element $\triangle x$ is proportional to the weight of the remaining portion $a - (x + \triangle x)$ of the string; hence if g denote the weight of a unit of the string, and e the index of elasticity peculiar to the substance, we have ultimately [DIFFERENTIAL CALCULUS] $\frac{dy}{dx} - 1 = g e(a - x)$, and therefore by the rules of the *Integral Calculus* $y - x = g e \left(a x - \frac{x^2}{2}\right)$, to which no arbitrary constant need be added, because y commences at the same point with x: if we now make $x = a$, we find that $g \frac{e}{2} \cdot a^2$ expresses the extension of the entire string.

Similar principles may be easily applied to determine the form of an elastic string suspended from two points, and stretched by its own weight; but in this case the curve (which differs from the common catenary) cannot be considered as accurately determined without taking into account the elasticity of inflexion as well as that of extension. The mere mathematical problem may be seen in most mechanical treatises. (Price's 'Calculus,' vol. iii. chap. 5; Poisson, 'Mécanique;' consult also Lagrange, 'Méc. Analytique,' for the method of introducing the condition of elasticity in a system at rest.)

An important practical branch of this subject, on the strength of beams, which has been much advanced by Mr. Peter Barlow, and the more recent experiments of Mr. Eaton Hodgkinson, of Manchester, we reserve for a future article. [STRENGTH OF BEAMS.]

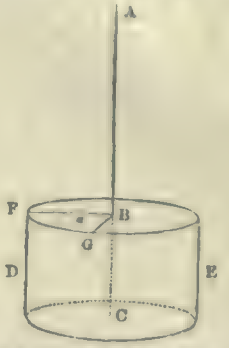
When a uniform elastic string, fixed at one extremity and stretched by a force applied at the other extremity, is abandoned to itself, it will return to its original form after a series of contractions and expansions, the force which solicits each point being proportional to its distance from its original place, though the successive oscillations go on rapidly diminishing in extent in consequence of the resistances encountered. The same law applies to the displacements of the molecules of elastic fluids and gases.

For the laws of the mutual impact of elastic bodies, see the article COLLISION, &c. If a body is attached to an elastic string, which at the other extremity is fixed, and be projected in any direction, the resolved part of the centrifugal force which acts in the direction of the length of the string tends to stretch it, and the centripetal force will be proportional to $r - c$, r being the length of the stretched and c of the unstretched string: this force is attractive when r is greater than c, and repulsive when less. Hence if we conceive a circle, of which the centre is the fixed point, and the radius equal to c, the portions of the orbit described externally to the circle are concave, and those internally are convex relatively to the centre of the circle, and there are as many points of contrary flexion [CURVE] as there are intersections of the trajectory and circle. Neither the law of the periodic times nor the form of the orbit is similar to those belonging to the earth and planets: the supposition, therefore, that attraction between the great masses which compose the solar system is conducted through the medium of interposed and invisible elastic strings is unfounded.

When an elastic string, fixed at one end, is bent by a weight or other force applied at a given point, the elasticity of inflexion acts normally at each point of the curve, and is some function of the curvature at that point. It is usual to suppose it proportional to the simple curvature. On this supposition the figure of an elastic lamina in a vertical position, fixed at its lower point, and bent by a small weight applied at the top, may be determined. This problem has been treated by Euler, Lagrange, and Poisson. The English reader may find the varieties of the elastic curve discussed in the appendix to Whewell's Mechanics.

The elastic force of a twisted string follows a law precisely similar to that of one which is only stretched: the latter is proportional to the extension, the former to the torsion. Thus, if a cylindrical elastic thread, fixed at one extremity, be twisted by a force applied perpendicularly to its length, any straight line taken along the surface of the cylinder will be converted into a helix; and with a double torsion the circular arc through which each point has been removed from its original place is doubled. And since this circular arc may be subdivided into any number of equal arcs, the successive resistances of the elasticity to the additional torsions are equal, supposing each preceding resistance to be sustained. Therefore the accumulated force of torsion is proportional to the angle through which an index would move if fixed at any point perpendicularly to the length of the cylinder, or in the prolongation of its radius: but this law has limits as well as that for the elasticity of extension; for the torsion may be continued until a strain is produced, when there will of course be an accompanying diminution of elastic force.

Let A B represent an elastic string, suspended vertically from the point A, and attached at B to a cylindrical body D E, of which the axis B C is in the direction of the string produced, the string being primitively in an untwisted state. Let the cylinder be turned round its axis through an angle F B G, or a, which measures the torsion generated in A B, and also the elastic force tending to bring the system back to its original state. Let the restraining force be now removed, and the cylinder, abandoned to itself, will return to its original place after a series of isochronous oscillations, which are gradually diminished by the resistance of the air and by the internal resistances of the molecules of A B during the processes of being twisted and untwisted.



Let δm stand for an element of the cylinder, situated at a distance r from its axis, and θ the angle of torsion, at any time after the commencement of this motion; then $-\frac{d\theta}{dt}$ is the angular velocity; and therefore the linear velocity of δm is $-r\frac{d\theta}{dt}$; the accelerating force or ratio of the increments of velocity and time is $-r\frac{d^2\theta}{dt^2}$; the force of torsion, being proportional to the angle θ, may be represented by $n\theta$ applied at a distance = unity from the axis of the cylinder, perpendicularly to the radius, the constant n being the force of torsion corresponding to an angle = unity. Now, by D'Alembert's principle, the impressed force, taken in a reversed direction, would make equilibrium with all the effective forces: that is, the force $-n\theta$, at a distance = unity, would produce an equilibrium with the forces such as $-r\,\delta m\frac{d^2\theta}{dt^2}$ acting on δm at a distance r; hence the corresponding moments, which are $-n\theta \times 1$, and the sum of all, such as $-r^2\,\delta m\frac{d^2\theta}{dt^2}$ must be equal, but of contrary signs; and since $\frac{d^2\theta}{dt^2}$ is the *common* accelerating force on all the particles δm at a unit distance, we need only take the sum of the products $r^2\,\delta m$, which is easily found in this case by the rules of the integral calculus, and is called the moment of inertia of the cylinder. Representing it by MK^2, where M is the mass of the cylinder and K its radius of gyration, we have the equation—

$$MK^2\frac{d^2\theta}{dt^2} = -n\theta$$

Put (for the sake of abridgment) $c^2 = \frac{n}{MK^2}$; then, by the methods for integrating differential equations, we find $\theta = A \sin.(ct + B)$, where A and B are arbitrary constants; and for the velocity $\frac{d\theta}{dt} = A\cos.(ct + B)$.

Now, we can determine the constants by the circumstances of the origin of the motion; for when $t = o$, we have supposed the initial torsion was a, or F B G, and $\frac{d\theta}{dt}$ was then nothing. Hence we have $a = A \sin B$; $o = \cos B$; therefore, squaring and adding, we have $A^2 = a^2$, and $A = a$. Similarly, by division, $\tan B = \infty$, $\therefore B = \frac{\pi}{2}$. The value of θ is therefore expressed at any time by $a \sin\left(ct + \frac{\pi}{2}\right)$, or $a\cos(ct)$.

When the cylinder makes half an oscillation the elastic thread is then perfectly free from torsion; and if T be the time of an entire oscillation, since θ then vanishes, we find $o = a\cos.\left(\frac{cT}{2}\right)$; therefore $cT = \pi$, and $T = \frac{\pi}{c}$, which shows that the successive oscillations are of the same duration, and that the square of the time of one oscillation varies directly as the moment of inertia, and inversely as the force of torsion, estimated at a given distance from the string.

The suspended body may be any other as well as the cylinder we have supposed, with manifestly the same results. For instance, in

Coulomb's torsion-balance it consists of a needle of gum-lac attached perpendicularly to the string, as B F in the above figure, and a small weight at B to steady the string; the law of the times of oscillation above found is sufficient to give the force of torsion in all cases if we know it in one. It is thus that Coulomb used his balance in finding the law of electrical attractions and repulsions; the electrised ball acted on, being attached to the end of the needle of gum-lac, was subjected to the joint action of electrical and elastic forces. [ELECTRICITY, COMMON.]

The range of the elastic force of fluids, in consequence of their great resistance to compression, is extremely limited, and therefore few ordinary phenomena of nature are dependent on this cause. The great pressure at considerable depths in the ocean must produce a corresponding increase of density in the lower strata, if it is not in a great measure compensated by the increase of temperature.

Water expands in volume by an increase of temperature, and contracts by a decrease; but it has this peculiar property, that at a temperature expressed by 39½ degrees of Fahrenheit's thermometer it attains a maximum of density. The quantity of water which at 60° would occupy 1 cubic foot, at 40° occupies only 0·9907 cubic foot; while at the temperatures both of 45° and 35° (its fluidity at the latter temperature being preserved by the avoidance of all agitation) the volume is 0·9991 cubic foot (Gilpin, 'Phil. Trans.,' 1792): the increase of volume at temperatures below 40° is ascribed to some tendency of the water to crystallise while it is still fluid.

The variations produced in the volume by variations of temperature, as well as the fact that water is a conducter of sound, and consequently that it possesses some elasticity, are to be considered as arguments that water may be capable of being compressed by mechanical means; but the quantities of compression which have been obtained by experiments made for the purpose are so small as to render it very difficult to determine its precise value.

In 1661 some members of the Academia del Cimento at Florence made experiments of different kinds in order to ascertain whether or not water was compressible; and one of these consisted in filling a hollow globe of silver with water at the point of freezing: an effort was then made, by blows with a hammer, to diminish the volume of the globe by altering its form, when it was found that the water escaped through the pores of the metal. The like experiment was made by Muschenbroeck in 1731 with a globe of gold, which was attended with a like result; and till the year 1762 it was considered that water was incapable of being reduced in volume by pressure. In that year Mr. Canton introduced water at a certain temperature into a glass tube, and having, by an application of heat, made the water fill the tube so as to expel the air, he sealed the tube hermetically: then, having reduced the temperature to its former value, he broke off the upper extremity of the tube in order that the atmosphere might press on the top of the column of liquid, when the height of the latter was found to be thereby diminished. The like experiment was tried with alcohol, oil, and mercury; and these fluids were found to suffer different diminutions of volume by the pressure.

It has been imagined that the apparent diminution of the volume of water was only the result of an expansion of the tube in consequence of the elasticity of the atmosphere, when the latter was allowed to enter it; but if such expansion alone had produced the effect it would have been the same, and would have caused equal depressions, in the columns of different kinds of fluid, whereas the depression of the water was about fifteen times as great as that of the mercury. There is little doubt, therefore, that the observed diminutions of height were results of the compressions of the fluids by the weight of the atmosphere.

The experiments of Canton show that, under a weight equal to that of an atmospherical column in its ordinary state (29½ inches of mercury), the compressions of the four following fluids, in millionth-parts of their volumes, and at a temperature equal to about 50°, are—

Alcohol	66
Rain-water	46
Sea-water	40
Mercury	3

The elasticity of a *perfect fluid* is such that its parts resist change of volume only, and not change of figure. The *compressibility* of a liquid is the compression produced by a unit of elastic pressure, and its *modulus* or *co-efficient of elasticity* is the ratio of the pressure applied to the liquid, to the accompanying compression, and is consequently the reciprocal of the compressibility, which latter is measured by an instrument called a PIEZOMETER. The empirical formula for the compressibility of water at any temperature between 32° and 128° Fahr. has been obtained by Mr. Rankine from M. Grassi's experiments; namely:—

$$c = \frac{1}{40(\text{T} + 461)\text{D}}$$

When c = compressibility per atmosphere required, T = temperature in degrees of Fahrenheit, and D = density of water at that temperature under one atmosphere, its maximum density under one atmosphere being taken at unity.

The elasticity of every *solid* is sensibly perfect when the strain on it does not exceed a certain limit. This has been proved even for solids like clay, for which there are limits, which, if a strain exceed, *set*, or permanent change of figure is produced. It has been shown by Mr. Hodgkinson that these limits depend on the duration of the strain, being less for a long continued strain than for a brief one, so that the elasticity of *volume* in solids is generally much more nearly perfect than that of figure. There exists one simple and uniform law for the elastic forces of dry air and all the permanent gases. From the experiments of Boyle, Mariotte, and Dalton, it is established that the elasticity, which is proportional to the pressure, is *inversely* as the volume, and therefore *directly* as the density, when the temperature is constant.

But an increase of temperature produces an increase of the elastic force of gases: or, which is the same, under a given pressure it expands the gas into a greater volume. Between the temperatures of melting ice and boiling water this increase of volume is proportional sensibly to the additional temperature, measured by a mercurial thermometer, as was well established by the experiments of Gay-Lussac; but by the more recent experiments of MM. Dulong and Petit, it appears that at much higher temperatures the degrees of the mercurial and gas thermometers no longer correspond; for the expansion of the mercury might be expected to become irregular when it tends to gassify, and therefore to have greater expansions for each degree of heat than in its liquid state.

In such experiments it is essential that the gas should be perfectly dry; for if not, the elastic force obtained will be that of dry air *plus* that of the contained aqueous vapour. For most observations on the latter we are indebted to the researches of Dalton, who observed that when the inside of a barometer is moistened, the elastic force of the vapour, occupying the space which is a vacuum in ordinary barometers, causes a depression in the column of mercury proportional to itself.

When a space is saturated with aqueous vapour or steam, the elasticity remains the same when the volume is diminished, the only effect of compression being to convert the surplus portion into water. The contrary holds generally in gases, as we have seen that their elasticity is inversely as their volume; but it is probable that with very high pressures, such as that employed by Mr. Faraday to liquefy carbonic acid gas, there exists a limit for each, beyond which it is impossible to render them more elastic by compression.

Moreover, the ratio of the elastic force of dry gas at the temperature of boiling water to that at the freezing point is by no means the same as in aqueous vapour; but at very high temperatures it seems probable that similar ratios would approximate. The following is a table of the elastic forces of the latter, corresponding to degrees of the centigrade thermometer:—

Temperatures.	Elastic Force, in inches.	Successive Ratios.
0	0·2	.....
6¼	0·297	1·485
12½	0·435	1·465
18¾	0·63	1·448
25	0·91	1·444
31¼	1·29	1·418
37½	1·82	1·411
43¾	2·54	1·395
50	3·5	1·378
56¼	4·76	1·36
62½	6·45	1·355
68¾	8·55	1·326
75	11·25	1·316
81¼	14·6	1·298
87½	18·8	1·288
93¾	24	1·277
100	30	1·25

The third column is given incorrectly in Biot's '*Physique;*' and it follows from inspection that the elastic force of steam increases nearly in a geometrical progression when the temperature is increased in arithmetical; from which property steam has now become a great mechanical agent.

When vapours are mixed with each other at the same temperature and in the same space, the elastic force of the compound is the sum of the separate elasticities, provided this sum is not sufficiently great to render any of the vapours liquid, and provided these vapours have no chemical affinity.

The atmosphere which surrounds the earth is endowed with an elastic power; and partaking, moreover, of the earth's diurnal rotation, its particles should, by their elasticity and centrifugal force combined, recede from the earth till the whole is dissipated in space. Such is not the fact; and hence it is inferred, either that at a certain elevation above the surface of the earth, the elasticity of the atmosphere is totally destroyed by the absence of caloric; or that beyond the stratum in which the centrifugal force of the particles is equal to their gravitation, there may exist, in a state of rest, an etherial fluid occupying the whole extent of space, and preventing the atmosphere from being further expanded by its own elasticity.

Now, by Mechanics, it may be found, that the distance from the surface of the earth to the stratum of the atmosphere in which the centrifugal force of the particles is equal to their gravity is about five semidiameters of the earth, at which height the density must be inconceivably small; and since it is not necessary to suppose that the etherial fluid beyond the atmosphere of the earth is more dense or more elastic than the atmosphere at that height, it may readily be admitted, that whatever may be the effect of such a fluid in resisting the motion of a comet, it can produce no sensible retardation of the movements of the planets.

The crepuscular light which has been observed at the cusps of Venus, and the changes which take place on the apparent discs of Mars and Jupiter, afford indications that those planets have atmospheres, though, with our instruments such atmospheres may not be rendered sensible by their action on transmitted light. If, about a planet, an atmosphere were formed in consequence of the attraction exercised by the planet on the etherial fluid supposed to fill all space, since that fluid may have no greater density and elastic power than the atmosphere of the earth at the height of five semidiameters of the latter above its surface, the attraction of the planet may be incapable of rendering it sufficiently dense to produce any sensible effect in refracting light to the earth. Again, the height and the law of the variations in the density of the strata in an atmosphere which may be formed about a planet by the vapours arising from waters existing on its surface, would depend on the temperature; and this we have no means of knowing: but assuming it to be equal to the mean temperature at the surface of the earth, the height of such atmosphere would be very small compared with that of the existing atmosphere about the earth. An atmosphere of either of the kinds here indicated would serve to account for the rare occurrence of remarkable refractions in the phenomena of the immersions and emersions of Jupiter's satellites, or the occultation of stars by the moon.

ELATERIN ($C_{40}H_{28}O_{10}$), a vegetable principle extracted from the wild cucumber (*Momordica Elaterium*). To obtain it the evaporated juice of the fruit is to be treated with water, and the residue with alcohol of specific gravity 0·825; the solution is to be evaporated to the consistence of a syrup; the elaterin then crystallizes; more is afterwards obtained by adding potash to the mother water; the matter obtained is to be purified by means of ether. Another process consists in pouring water into the concentrated tincture of elaterium, by which the elaterin is precipitated in the state of small silky crystals.

Elaterin has a bitter and somewhat styptic taste. It is insoluble in water, and in dilute acid and alkaline solutions; it is soluble in five parts of cold alcohol and two parts of boiling alcohol, and also in ether and fixed oils. It melts at a few degrees above 212°, and at a higher temperature it is volatilised in very acrid white vapours.

Concentrated acids decompose it: nitric acid converts it into a yellow gummy mass; sulphuric acid dissolves it, and assumes a deep blood-red colour.

Elaterin acts strongly as an emetic or purgative, in doses of 1-12th or 1-10th of a grain.

ELATHIN. A chemical product of uncertain composition, obtained by acting upon acetone with sulphur and ammonia.

ELAYL. [ETHYLENE.]

ELAYL-OXALIC ACID ($C_8H_4O_6$,2HO). An acid, isomeric with succinic acid. It has hitherto been little studied.

EL DORA'DO, literally the golden country, was the name given by the Spaniards in the 16th century to an imaginary region somewhere in the interior of South America, south of the Orinoco and between that and the Amazon river, where gold and precious stones were supposed to be as common as rocks and pebbles in other countries, and to be had for merely picking them up. The first notion of this story was communicated by an Indian Cacique to Gonzalo Pizarro, brother of the conqueror, who sent his companion, Francisco Orellana, down the Amazon river to discover this wonderful land. Orellana followed the course of the Amazon down to the sea; but though he did not find El Dorado, still he countenanced the report of its existence. The temper of mind of the Spanish conquerors and discoverers of America seems to have been singularly fitted for credulous belief in all wonderful reports. The story of El Dorado continued to be accredited; a Spanish adventurer was said to have reached the capital of this enchanted region, called Manoa, and wonderful tales were told of its splendour and its wealth, far surpassing those of Peru. The Spanish governor of Guiana was also styled governor of El Dorado, because the latter country was reckoned to belong to his jurisdiction. Raleigh was so persuaded, or pretended to be persuaded, of the existence of this wonderful country, that he fitted out several expeditions for the purpose of discovering and conquering it for England; his last attempt in 1617 involved him in hostilities with the Spaniards of Guiana, which ultimately led to his death on the scaffold. [RALEIGH, SIR WALTER, in BIOG. DIV.]

ELEATIC PHILOSOPHY has its name from Elea (called by the Romans, Velia), a Grecian colony on the western coast of Lower Italy, where Xenophanes of Colophon settled in his old age (about 530 B.C.), and founded a school distinguished by its bold attempt to construct a system of the universe upon metaphysical principles. The theory was brought to perfection by Parmenides, but it also reckons among its members Zeno, Melissus, and Empedocles, who, however, only gave a further development to particular principles; the labour of Melissus being mainly confined to the defence of those positions which were opposed to the Ionian physics, while Zeno and Empedocles exhibit the opposite aspects of the theory, the former confining himself to its doctrine of the supra-sensible, the latter to a detailed application of its physiological views.

In its formation it was subsequent to the Ionian and Pythagorean schools, and was so far a consequence of them as it thought necessary to submit to investigation the legitimacy of the principles upon which they had proceeded. The problem which they had proposed to themselves was, assuming the possibility of a beginning of motion and of production and decay, to determine the first ground or grounds of all that comes into being. This assumption the Eleatæ attacked as irreconcilable with that idea of the reason which involves the law of casuality, the Eleatic expression for which was "out of non-being being cannot come," and its later and more general formula, "ex nihilo nihil;" and as no distinction had as yet been made between the efficient and material causes, they necessarily arrived at the conclusion that the world had not a beginning.

Parmenides drew a strong distinction between the ideas obtained through our reason and those derived from our senses; or between truth and opinion; but with him religious considerations predominated, and in order to refute the unworthy conceptions of the Deity to which polytheism had given rise, he showed from the very notion of God that he is necessarily one. The notion of Deity, he argued, implies his infinity and eternity, but there cannot be many infinite beings; the eternal and infinite God is therefore one. But from the denial of production it followed that the world is eternal. Now an eternal world would equally limit the eternal God: the co-existence therefore, of the two, separately and independently of each other, is impossible; consequently the world and the Deity are one. This result is the foundation of the so-called error of Pantheism; but it was only by such an error that man could arrive at a right and worthy conception of the Deity, which it is the merit of the Eleatæ to have distinctly propounded.

From the position that God or the world is one, it necessarily followed that our conceptions of sensible things singly are imperfect and insufficient to bring us to a knowledge of the All or of God. Man, consequently, is placed in a painful situation, desiring on the one hand to know God, on the other to look to individual phenomena. Attention was thus awakened to the opposition which exists between the pure truth and the sensible appearance, and the Eleatæ were the first to advance a systematic theory of human knowledge; and although its object was to deny the validity of the testimony of sense and experience, and to ascribe to the reason exclusively the merit of arriving at the truth without any attempt to reconcile appearance and reality, it nevertheless constituted a most important advancement of the philosophy of the period, and so completed its edifice as a system by contributing the dialectical or logical portion; the Ionians and the Pythagoreans having respectively constructed the physical and moral parts.

In conclusion, we must observe that the history of this as well as of the other early schools of Grecian philosophy is both obscure and imperfect, since of the written works of its several members we only possess a few and unconnected fragments. And it must be carefully observed that though Plato in his 'Parmenides,' pays a high tribute to his dialectical talents, we must not take his representation of the opinions held by Parmenides.

ELECAMPANE. [INULA.]

ELECTION (Lat. *electio*), in divinity, is a doctrine which, on the authority of Scripture, and as a consequence of the omniscient and prescient attributes of God, teaches that from all eternity the destiny of every individual of mankind was determined by an immutable decree, some (the elect) being ordained to eternal salvation, while others (the reprobate) are left to inevitable and eternal damnation. The term election is often considered as but another name for the doctrine of predestination, both implying that man is subject to a certain predetermined fate. This doctrine in modern times is associated constantly with the name of Calvin, though similar notions were maintained or opposed among the philosophical and religious sects of the ancient Gentiles, Jews, and Christians. The Essenes were believers in absolute preordination. The Sadducees rejected it, and adopted the doctrine of moral freedom. The Pharisees, in a theory of syncretism, endeavoured to reconcile and combine the two extremes. (Josephus, 'Antiq. Jud.') The Stoics insisted upon the doctrine of predestination or necessarianism; while the rival sect of Epicureans maintained that of the perfect free agency of man and the contingent nature of events. The Gnostics taught that human souls, according as they emanated from the good or bad principle, were destined to happiness or misery. In the systems of Manes (Manichæism), Marcion, Cerdon, and others of the 2nd century, similar doctrines were enforced concerning the fixed inevitable fate of men. Throughout the first four centuries the pagan philosophers, especially those of the Stoical school, opposed the dogmas and miracles of Christianity by alleging the principle of necessity as exhibited in the immutable series of causes and effects, or antecedents and consequents, in the physical and mental phenomena of nature, and the ignorant populace were confirmed believers in the influence of fortune and fatality. Justin Martyr, Irenæus, and most of the Greek fathers, in defending the Christian system, resorted therefore to arguments tending to establish anti-predestinarian doctrines. Origen, in the 3rd century, had taught that man, in his moral and religious agency, is not necessitated by omniprescient decrees of God. His tenets were adopted in Palestine, and throughout the East, especially by Chrysostom, Isidorus, Theodoret, and the other Greek fathers; and Pelagius, an English monk, proceeding on their authority, promulgated in the first half of the 5th century the sectarian theory designated Pelagianism, which asserts free agency, moral responsibility and perfectibility, making good works meritorious, and denouncing the predestinarian doctrine of imputed guilt and inherited depravity. (Pelagius in Pluquet's 'Dict. des Hérésies.') St. Augustine was among the most strenuous opponents of Pelagius, and adduced abundance of scriptural authority to show the absolute omnipotence, the omniprescience, and consequently the preordination of God, with respect to the characters and destiny of men; showing some to be elected by the divine will as objects of especial grace, and others to be abandoned to the perdition which through Adam is merited by all. (St. Augustine, 'De Gratia, De Peccat. orig., De lib. arbitr., De Dono Perseverantiæ.') The arguments of St. Augustine occasioned the formation in the 5th century of a sect in Africa called Predestinarians, the tenets of which were zealously propagated in Gaul by a priest named Lucidus, who was excommunicated and anathematised by the church in council. (See the treatise of Père Sirmond on this heresy, and the replies of the Jansenists and divines of Port Royal.)

In the 9th century, the Predestinarian controversy was revived with great enthusiasm by Gottescalque, a French Benedictine monk, who was condemned, and terminated his life in a dungeon, for teaching the "five points" concerning election, which subsequently gained for Calvin so much celebrity. Gottescalque was answered by Scotus Erigena, and many others. (Dufresnoy, 'Tablettes Chronolog.') This incomprehensible subject formed one of the great points of subtle disputation in the scholastic theology; it was discussed by 'the Angelic Doctor,' Thomas Aquinas, and others, in the 13th century. Whether God's election was before or after the prevision of human merits was a standard thesis for the exercise of syllogistic skill (electio ante vel post prævisa merita). Aquinas sustained the doctrines of Augustine, and the controversy was subsequently carried on in the 16th century between his followers (the Thomists) and the adherents of Louis Molina (the Molinists). When Luther began to form his opinions, he perceived that nothing could so effectually demolish the Roman Catholic doctrine of justification by works as the predestinarian theory of St. Augustine, which he therefore enforced in his writings; but finally he was induced by Melanchthon to mitigate the rigour of his opinions concerning man's passive subjection to God's eternal decrees. By the Socinians the certain prescience of future events by the Deity is denied, and the divine decrees are maintained to be merely general, and not specially relative to particular persons. The system of Calvin is set forth in his great work entitled 'Institutes of the Christian Religion' ('Institutiones,' &c.), in which he states that "no one desirous of the credit of piety can dare to deny God's predestination of some to eternal happiness, and of others to eternal damnation;" that "every man is created for one or the other of these purposes." God having from all eternity fixed the destiny of every individual of the human race, all of whom, in consequence of Adam's offence, have been, are, and to the end of time will be, under the curse and wrath of God, and justly subject to everlasting punishment; that salvation depends wholly on God's will; that particular persons, without any regard whatever to their merits or demerits, are elected, or rejected for ever; and that God is an absolute, tremendous, and incomprehensible Judge. Such propositions, it must be confessed, are sufficiently mysterious and fearful to overwhelm the timid with despair, and excite the bold to inquire if they are founded in truth. One of the ablest works in confutation of Calvin is Dr. Whitby's discourse on the five points of his system, which are as follows: 1. God, before the creation, was pleased to choose, without prevision of merit, some of mankind to enjoy everlasting happiness, and others to suffer everlasting misery. What was certainly foreseen must certainly come to pass, as the prescience of the omnipotent and omniscient Being must be coincident with, and not by possibility antecedent to, his decrees. 2. Atonement was made by Christ only for the sins of the elect. His death did not make the salvation of all *possible*, and dependent on the performance of certain conditions; for if God intended salvation for all, doubtless all must be saved; and if Christ died for all, he died in vain for many, which is a supposition absurd and impious. 3. By original sin, that is, the imputation of Adam's guilt, all are by nature in total depravity, which justifies the consignment of the whole human race to eternal misery, and makes the election of some to happiness an act of God's especial grace and good pleasure. 4. All the elect are effectually called at some point of time in life when the influence of the divine grace is first communicated. 5. As all who are not elected must be damned, so all those who are elected must be saved: irremissible grace necessitates all their actions, and inevitable salvation must terminate their "final perseverance."

The following are some of the scriptural authorities alleged in support of these doctrines: Ephesians i. 4, 5, 11, some chosen before the foundation of the world; predestinated according to God's pleasure: Acts xv. 18, God's foreknowledge: Rom. viii. 29, 30, 33, those foreknown, predestinated, called, justified, and glorified, are God's elect; Math. xxv. 34, to inherit a kingdom eternally prepared for them: Acts xiii. 48, those ordained to eternal life believe; Rom. ix. 11, 18, 21, 22, 23, election before birth, and not according to works; God's power absolute; mercifully favours some and hardens others. Divine election is considered to be shown in the acceptance of Abel, and the rejection of Cain; in God's love of Jacob, and hatred of Esau (Malachi i. 2, 3); in the two men in the field; the two women at the mill; and the two in a bed, of whom one was taken and the other left (Luke xvii. 34, 35; Matth. xxiv. 40, 41).

Arminius, a professor in the University of Leyden, became, at the commencement of the 17th century, the chief of Calvin's opponents, who were thence called Arminians, and Remonstrants, from the remonstrance which they addressed to the Dutch government against Calvinistic intolerance. But the rigid Calvinists, headed by Goar (Goarites), being by far the most powerful party, Arminius and his adherents were condemned at the general synod of Dordrecht, convened for the purpose in 1619. (Scott's 'Synod of Dort,' pp. 112–124.) At this synod the standard points of strict Calvinism, with respect to election, were determined upon and established. That the homilies and articles of the English church, especially the seventeenth, are confirmatory of the Calvinistic views of election, is beyond dispute, though many Arminian expositors have made laborious efforts to explain away their obvious original purport. Bishop Burnet, in his exposition of the Articles, observes that the seventeenth, on Election and Predestination, "has given occasion to one of the longest, the subtilest, and the most intricate of all the questions in divinity." It displays in fact the *medulla* of Calvin's Institutes, precisely involving all the doctrinal particulars of his "five points," and asserting that, to the *elect* predestination "is full of sweet, pleasant, and unspeakable comfort; while to the *reprobate* it is a most dangerous downfall, whereby the devil doth thrust them into desperation and wretchedness." Baxter endeavoured to reconcile the doctrines of Calvin and Arminius. Arnauld, in his treatise on the subject, contends that the Calvinistic predestination directly overthrows all the principles of morality; though many others, including Dr. Chalmers, in his lectures on Predestination, assert the contrary. To enumerate the various modifications of this doctrine, which at different times have been maintained by distinguished theologians, would be endless. Some, as Origen and the Catabaptists, have denied that any one is predestined to perdition, and contended that salvation will be finally extended to every one of God's creatures, including the devil and all his angels. (Bullinger, 'Contra Catabap.') The number of writers on the subject have been very great, and are continually increasing, but the following references may be useful to the studious inquirer:—

(Cudworth's *Free Thoughts on Election*; Diderot, *Encyclop.*, articles Predestination, &c.; Bossuet, *Hist. des Variations*, liv. 14; *Westminster Assembly's Confession of Faith* (Calvinistic); Mosheim's *Eccles. Hist.*, vols. iii. and iv.; *Authentic Documents relating to the Predestination Controversy under Queen Mary*, by Archbishop Lawrence, 1819; Jonathan Edwards's *Freedom of the Will*, and other of his works; the works of Whitefield and Wesley; and the *Theological Essays* of the Rev. F. D. Maurice.)

ELECTION (law) is when a man is left to his own free will to take or do one thing or another which he pleases (*Termes de la Ley*); and he who is to do the first act shall have the election. As if A covenants to pay B a pound of pepper or saffron before Witsuntide, it is at the election of A at all times before Witsuntide which of them he will pay; but if he does not pay either before the time fixed, then it is at the election of B to sue for which he pleases. So, if a man give to another one of his horses, the donee may take which he chooses; but if the donation be that he will give one of his horses (in the future tense), then the election is in the donor.

Courts of equity frequently apply the principle of election in cases where a party has inconsistent rights, and compel him to elect which he will enforce: as, if A by his will assumes to give an estate belonging to B to C, and gives other benefits to B, B cannot obtain the benefits given to him by the will unless he gives effect to the testator's disposition to C. The principle of election is equally recognised in courts of law, though they are seldom called to adjudicate upon it, except where the alternative is very distinct, or the party has already elected. Indeed this principle is of universal application, and prevails in the laws of all countries; it is applicable to all interests, whether of married women or of infants; to interests immediate, remote, or contingent; to copyhold as well as to freehold estates; to personalty as well as to realty; to deeds as well as to wills.

Courts of equity also will compel a plaintiff suing at law as well as in equity, or in a foreign court as well as in the court in England, for the same matter at the same time, to elect in which court he will proceed, and will restrain him from pursuing his rights in all others. There are some exceptions to this doctrine, as in the case of a mortgagee, who may proceed in equity for a foreclosure, and on his bond or covenant at law at the same time; but this arises from the difference of the remedy, and from the original agreement to give the concurrent remedies: and even in such a case a Court of equity will restrain a mortgagee from enforcing his judgment at law upon the bond or covenant, if he is not prepared to deliver up the mortgaged property and the title-deeds belonging to it.

On Election under a will in the Roman law see 'Dig.' xxxiii. tit. 5, De Optione vel Electione Legata: as to the French Law, see the 'Code Napoléon,' art. 1189, &c., Des Obligations Alternatives; and for the law of Scotland, 'Ersk. Inst.,' lib. iii. tit. 3, 8, and 9.

ELECTION COMMITTEES. The trial of charges alleged on petition in respect of the election of a member of parliament, or the return made in such case to the Speaker's writ, used to be had before the house itself, and of course, became the occasion of party manœuvre and contest; but in the year 1770, the statute, known as the Grenville Act, had the effect of sending all such petitions to be tried by a select committee of members chosen upon a plan which, in substance, continued in force till the year 1839. The impartiality and justice of the system adopted in the latter year met with general approval, and continues with slight modifications to be in the main the same that is now applied in the case of controverted elections by the 11 & 12 Vict. c. 98.

The chief features of the existing system for the appointment of such tribunals are these: The Speaker at the beginning of the session of parliament, by his warrant, appoints from the members of the house, six gentlemen willing to serve, who have not been petitioned against, and are not themselves petitioners against any election, and these, if not objected to within three days from the time of the warrant being laid on the table of the house, become "the general committee of elections" for the session. Four members form a quorum, and no business may be validly transacted by a smaller number. This committee may be dissolved upon their own report, that more than two of their number are absent, or that there is irreconcilable difference of opinion among them, or upon resolution of the house for that purpose. Meanwhile, they are each sworn at the table "truly and faithfully to perform the duties belonging to a member of the said committee, to the best of his judgment and ability, without fear or favour," and to the committee thus formed are referred all election petitions, the Speaker keeping them duly informed of the state of the recognisances entered into by the petitioners, and of deaths, vacancies, or declarations on the part of members of their intention not to defend their seats.

The duty of this general committee is to appoint the committees for the trial of controverted elections, called therefrom "election committees," taking the petitions in their order from the list submitted to them, and selecting the committee from the panels framed in the following manner:

First, from the list of the house are struck the names of members exempted from serving on election committees, because they are more than sixty years of age, or because they are in high office under the crown, or for such other special reason as may satisfy the house; and also, the names of members disqualified, either because they have petitioned against a return, or are themselves the objects of such petitions.

Secondly, from the list, after it has been thus summoned, the general committee select "the chairmen's panel," consisting of eighteen, or a smaller number of members, to act as chairmen of election committees for the remainder of the session, unless discharged from their duty by the house. Vacancies created in that or in any other way being immediately filled by new appointments.

Thirdly, the residue of the general list of members is divided equally into five panels, which take order, as first panel, and so on according to a ballot conducted by the clerk at the table of the house. From these are to be chosen the members to constitute the election committees, and each panel in its own order is then, for the week, the panel that is liable to furnish members for such tribunals.

The general committee of elections having determined the time for appointing a committee to try the controverted election next in order, give 14 days' notice of the day so fixed by them. Six days before the time so fixed, the parties petitioning are required to give in a list of the voters objected to, and also of the several heads of objections on which they mean to rely in support of their petition. On the day fixed for the appointment of members, the general committee is attended by the parties and their agents; they are furnished with the names of the chairman and the four members chosen to try the matter of their petition, and with this list they withdraw for half an hour to consider what objections, if any, they have to any of the names that are upon it. It is a rule of the house that no member may serve on an election committee who has voted at the election itself, or is the person on whose behalf the seat is claimed, or is related either to the sitting member or the person on whose behalf the seat is claimed, by kindred or affinity in the first or second degree, according to the Canon law. At the expiration of the half hour, or as soon after as suits the convenience of the general committee, they return to state their objections to the list of names, and if four members of the general committee agree that the objections are well founded, the parties withdraw and the committee proceed anew to select other names for any of the four which have been struck out; or if it be the chairman that is objected to, the gentlemen forming the chairmen's panel proceed to a new election: and the same right of objecting to the new list may again be exercised by the parties who are called together *toties quoties* to signify their assent or dissent accordingly.

When an unobjectionable committee has been obtained, the members of it have notice from the committee-clerk in writing forthwith, the committee is reported to the house, and the members are bound, under peril of censure or of being committed to the custody of the Serjeant at Arms for default, to attend in their places in the house on the next sitting day at or before four o'clock, in order to be sworn at the table "we and truly to try the matter of the petition referred to them, and a true judgment to give according to the evidence."

The election committee meet by order of the house at a time fixed, within four-and-twenty hours of their being sworn to proceed with the business of their appointment, and they continue to meet daily, except on Sundays, Christmas, and Good Friday; having no power to adjourn for more than twenty-four hours at a time without leave obtained from the house for special reason, or to permit the absence of any one of their number. If one of them should nevertheless absent himself without the leave of the house, his sickness, if that is the ground, must be verified to the house upon affidavit of his medical attendant; or if it is for any other cause, that too must be verified upon oath, otherwise the defaulting member may be ordered into custody, or censured as the house thinks fit. The committee cannot proceed to business any day until their number is complete, and if it remains incomplete for an hour they must adjourn, and report the cause of it to the house; and the committee, if reduced to less than three members for three successive sitting days, is *ipso facto* dissolved, and their proceedings are void. The general committee in that case appoint a new committee to try the petition. It is always, however, in the power of the parties before it to consent to go on with a committee deficient in numbers, even when reduced to one.

These committees take evidence on oath, hear the parties by counsel, decide by a majority, the chairman always voting, and having a casting vote in case of an equal division, and their final decision is reported to the house upon the following questions: Whether the petitioners or the sitting members, or either of them, be duly returned or elected? or, Whether the election be void? or, Whether a new writ ought to issue?

A special report upon the case, or any particular feature of it, or person connected with it, such as may be the foundation of ulterior proceedings, that is, by way of criminal prosecution, or commission of inquiry, should the house deem it desirable, may be adopted by them in addition to their report on the main question before them. Until they have reported, and so become *functi officio*, even a prorogation, though it may suspend their proceedings, does not dissolve the committee.

ELECTION OF MEMBERS OF PARLIAMENT. Under COMMONS, HOUSE OF, this subject has been treated generally; but we may add here that recently several statutes have been passed directed to obtaining what is called "purity of election." The merely formal proceedings are still taken under the original Reform Acts; but in order to restrain bribery, treating, and intimidation, the returning officers are now required annually to appoint *election auditors*, through whom alone can accounts in respect of the election be paid by the candidates. Stringent provisions have been made for inquiring into charges of corrupt practices, by committees of the house, sworn to the performance of their duties. Bribery, if proved, involves the disqualification of the elector, and the unseating of the member chosen, if the charge is brought home to him. The candidate is required to appoint his own agents, in writing, so that they may be known; and to send all accounts and a note of all his disbursements to the election auditor; which, when audited and paid through the auditor, are to be published in the local newspapers. It may be added here, however, that both the method of proceeding at elections, and the principles which ought to guide legislation on that subject are at present quite undetermined, the recent Acts of Parliament being only of temporary operation and of an experimental character. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. i. p. 166.)

ELECTORS. [COMMONS, HOUSE OF.]

ELECTRIC. Substances capable of producing electricity by friction were, in the infancy of electrical science, arranged in a class in the order of their supposed susceptibility to excitement, and were called *Electrics*, or *Idio-electrics;* while a large number of bodies, including all the metals, were supposed to be unexcitable by friction, and were hence called *Anelectrics* or *Nonelectrics.* When, however, the electric conducting power of bodies became known, it was seen that an uninsulated rod of metal, for example, could not be excited permanently, on account of the electricity being conducted away as fast as it was formed. By furnishing the metal with a rod of glass, it was found to be capable of excitation by friction, and of retaining its charge, just as a tube of glass would do. In this way it was ascertained that all solids were capable of being electrified by friction, although in different degrees, and such lists as the following were constructed to represent the order of excitability—the most excitable coming first:—

LIST OF ELECTRICS.

Shell-lac, amber, brimstone, jet.
Resins, pitch, wax.
Gums, camphor, caoutchouc, gutta-percha.
Gun-cotton, collodion paper.
Glass, and all vitreous and vitrified substances.
The diamond, agate, and most precious stones.
Tourmaline, and other crystalline, transparent, argillaceous, and siliceous gems and stones.
Bituminous substances.
Silk, dry animal furs and skins, hair, wool, feathers, paper, porcelain
Turpentine, and various oils and fatty fluids.

Dry gases, atmospheric air, highly elastic steam.
Ice at 0° Fahr.

The substances in the above list are also called *non-conductors* or *insulators*.

The following is a list of *electrical conductors*; or, as they are sometimes called, *non-electrics*.

LIST OF NON-ELECTRICS.

Metals.
Well-burnt charcoal.
Plumbago.
Acids, acid solutions, and saline fluids.
Water, and moist vegetable matter.
Living animal matter.
Flame, smoke, steam.

The term *electric*, although having a definite substantive meaning, is, from the general love of contracting long words, often used as an adjective in the place of *electrical*. In arranging the following articles, we have consulted the reader's convenience by restoring in many cases the words to their original meaning, although in compliance with custom we shall use the expression *electric telegraph*, &c., instead of *electrical telegraph*, &c.

ELECTRICAL ALARUM. [TELEGRAPH.]

ELECTRICAL ATTRACTION. Under this designation it is intended to notice the apparent attractions and repulsions which take place when bodies are in particular states with respect to electrical power.

From a very early time it was known that amber, when excited by being briskly rubbed, seemed to draw towards it such light bodies as straws and feathers: and the phenomenon, as well as that of an apparent repulsion, is now exhibited in a more striking manner by presenting a cylinder of excited glass or of excited wax to a pith ball or a downy feather suspended by a silk line. [ELECTRICITY, COMMON.]

In attempting to explain by what means these actions might arise, it is imagined that there may exist in all material substances a fluid, or fluids, whose particles exercise upon one another attractive or repulsive powers, while a mutual attraction may take place between the fluid particles and those of the substance with which they are combined.

The hypothesis of Watson and Franklin was that there exists but one kind of such fluid: it was supposed that, in exciting glass and some other bodies by friction, the fluid was abstracted from the earth through the material by which the friction was produced, and accumulated upon the surface of the body, which thus obtained more than its natural quantity. It was supposed that this excess readily passed into any body near it, provided the latter had less than, or only its natural quantity, or at most had not so great a quantity in proportion to its magnitude. In the excitement of resinous bodies it was supposed that the fluid passes from those bodies, through the material employed in the friction, to the earth; and thus the resinous bodies were supposed to have less than the natural quantities. Hence arose the distinction between positive and negative, or redundant and deficient electricity; and the theory of Æpinus and Cavendish relating to the distribution of electricity on the surfaces of bodies is in conformity with this hypothesis. But the hypothesis is open to some objections; thus, when bodies are deprived of the fluid which, when they are in the ordinary state, is combined with them, they are observed to repel each other mutually; and it must therefore be inferred that the particles of bodies exercise upon each other a strong repulsive power, a circumstance which can scarcely be reconciled with the general attraction existing among the bodies in nature, or with the cohesive power by which the particles of all bodies are held together. It is moreover impossible to conceive, as Biot observes, why negative electricity, that is, a mere absence of fluid, should be developed on the surfaces of bodies according to the hydrostatical laws by which a real fluid would be developed.

To this hypothesis succeeded that which is now generally received. It was proposed about the same time by Symmer in England and Du Fay on the Continent, and consists in the assumption of two fluids, of directly opposite qualities, existing at the same time in combination with the particles of all bodies in nature: the particles of each fluid are conceived to exert on one another a strong repulsive force, while the particles of the unlike fluids mutually attract each other. The experiments of Coulomb with the electrical torsion balance have proved that the attractive and repulsive forces vary in intensity inversely as the squares of the distances between the particles, and that at equal distances the attractions and repulsions are exactly equal.

The manner in which the mutual actions of electrical particles produce the phenomena of attraction or repulsion in bodies with which they are combined, omitting the consideration of the effects arising from the decompositions of the natural electricities of the bodies, is conceived to depend in part on the pressure of the atmosphere, and in part on the conducting powers of the bodies. Thus, if by any excitement electrical particles be collected on the surface of two bodies (suppose two spheres) which are non-conductors, they will be retained there, by the pressure of the surrounding air, and by the impermeability of the material: hence the bodies must take the motions which result from the repulsion or attraction of the fluids on them, according as those fluids are of the same or of unlike kinds. If one of the bodies be a conductor and the other a non-conductor, and they be both charged, for example, with electricity of the same kind, while that which is on the surface of the latter suffers little change of disposition, that which is on the other moves freely through its substance, and is, by the mutual repulsion of the particles, driven in abundance to the opposite side, so as to be more dense, or to form a thicker stratum there than on the side nearest to the non-conductor. But the re-action of the electrical fluid against the surrounding atmosphere being proportional to the square of the thickness of a stratum, it follows that there is an excess of force tending to make the conducting body recede from the other; and it is easy to perceive that a like explanation may be given of the contrary movement which takes place in the conducting body when the two are charged with unlike kinds of electricity. These views, however, have of late years been greatly modified, in consequence of the researches of Faraday. [ELECTRICITY, COMMON.]

The circumstances relating to the distribution of electricity on the surfaces of bodies agreeably to the hypothesis of two fluids, have been determined with the aid of a most refined analysis, by La Place, Ivory, and Poisson; and the 'Theory of Electricity,' in the 'Encyclopædia Metropolitana,' contains an investigation of the distribution on the surfaces of spheres. The results are there computed numerically, and compared with those which Coulomb has obtained by direct experiment, and the discrepancies are found to be only such as may fall within the limits of the unavoidable errors in the experiments themselves.

When a magnetised body is placed near one which is not so, a decomposition of the natural magnetism in the latter takes place, similar to that decomposition of the electrical fluids which occurs when a body in its natural state is brought near one which has been excited by friction [ELECTRICITY, COMMON], and all the phenomena exhibited by magnetised bodies on one another are capable of being explained on the hypothesis of two fluids, the particles of which repel or attract one another according as they are of the same or of unlike kinds, the intensities of the forces being inversely proportional to the squares of the distances.

The hypothesis of two fluids, moving in opposite directions, is also adopted in order to explain the phenomena of galvanism and electro-magnetism; that which is considered as positive flowing from the zinc, through the acid, to the copper, and that which is called negative, from the copper, through the acid, to the zinc; but the discovery that a balanced magnetised needle was affected when placed in the vicinity of the wire connecting the opposite ends of a galvanic battery, has given rise to an hypothesis that the power supposed to exist in what was called by the general name of an electric fluid was produced by a spiral motion of the fluid current about the conducting-wire, or about the particles of a magnetised needle.

Oersted, the discoverer of the electro-magnetic action, conceived that, when the circuit was completed by the wire passing from the zinc end to the copper end of a battery, the positive and negative fluids which, if unimpeded, would flow in straight lines, were compelled by acting against each other to move spirally about the wire; and this opinion is still generally held, it being supposed that the turns of the spiral are very near one another, so that they may be considered as circles whose planes are perpendicular to the axis of the wire. The course of either current, according to the explanation given by Mr. Barlow, may be easily understood from the following description, which relates in particular to that which is called positive: Let a conducting wire be imagined to be so bent that part of it shall be in a vertical position, and shall pass perpendicularly through the paper, the part above proceeding from the zinc or positive end of the battery, and the part below to the copper or negative end; the current of positive electricity being thus from above downwards: imagine also, a small needle whose north and south poles are represented by *n* and *s* to be horizontally balanced on a pivot and placed successively at different points in the circumference of a circle described about the intersection of the wire with the paper. Then, the directive power of the earth on the needle being neutralised by the presence of a magnet, the line *n s* will assume in every part the position of a tangent to that circumference, the direction *n s* being always such as it would be if the point *s* revolved in advance of *n* round the axis of the wire in the same order as the hands of a watch move. [ELECTRO-DYNAMICS.] The negative current may be understood to be revolving at the same time in like manner, but in a contrary direction. The currents thus revolving are supposed to act on the particles of the magnetised needle, disposing them to arrange themselves parallel to its axis, and so as to bring the latter in the position of a tangent to the curve described by the fluid about the wire.

The hypothesis of Ampère differs from that which has been just stated: this philosopher having formed the conducting wire into two parts, which could be so connected with the opposite poles of a galvanic battery that the current of positive electricity might be made to pass along the two parts in the same direction, or in contrary directions, found that, in the former case, the wires (which were delicately suspended in horizontal and parallel positions) seemed to attract, and in the other case to repel, one another. He from thence inferred that the fluids passed in rectilinear directions, or parallel to the axes of the wires, and that the particles were so polarised as to present to each other, laterally, when they moved in the same direction, sides which had powers of attraction; and when they moved in contrary directions, sides which had powers of repulsion: he further supposed, in order to account for the effect of the wires on a magnetised needle, that magnetic currents revolve about every particle or rather every physical point of a magnetised body, as it were in the plane of an equator to an infinitely small sphere; and he assumed that the fluid in the conducting wire of a battery exerts actions upon these revolving currents, by which the planes of the revolutions are brought into such positions that, if produced, they would pass through the axis of the conducting wire. It is evident however that the effect thus produced on the needle is the same as that which was before described; for, as the planes of the revolving currents are supposed to be perpendicular to the axis of the magnetised body, that axis must tend to place itself in the direction of a tangent to a circle supposed to be perpendicular to the axis of the conducting wire of the battery.

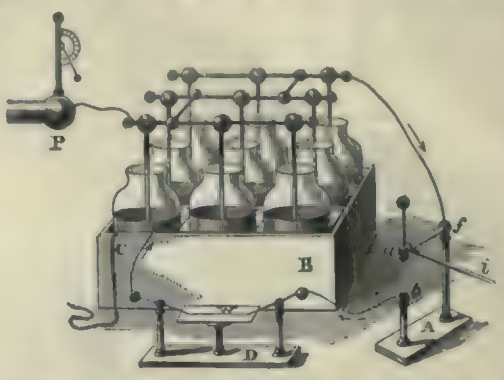
It has been ascertained that the current of electricity produced by the electrical machine causes deviations in a magnetised needle; and it is now generally believed that the electric, galvanic, and magnetic fluids, if such there be, are identical. [ELECTRICITY.] An experiment made by Mr. Faraday, in which a magnetised needle caused to float on water was found to enter a glass tube having its axis on a level with the surface and about which a galvanic conducting wire was spirally wound; while such magnetised needle would not enter the bore of a hollow magnet placed in the same situation as the glass tube—seemed however to show that the nature of the galvanic and magnetic fluids was not absolutely the same. But M. Ampère, in explanation, has observed that the result of the experiment is not inconsistent with the hypothesis of identity; since, when the wire is coiled about the glass tube, the needle is within the electric current, whereas it is outside of the currents about the particles of the magnetic tube.

ELECTRICAL BATTERY, a number of cylindrical vessels of glass, each precisely similar to the usual *Leyden jar* [ELECTRICITY, COMMON], the open top being covered by a plate of wood, into which is screwed the foot of a brass pillar which terminates at the top with a ball of the same metal, and at the bottom with a chain, which descends to the lower part of the jar inside; or, as in the annexed figure, the rod may be solid throughout its length, or only branch out a little at the bottom to serve as a support, in which case the jars do not require wooden covers. Both the inside and outside of each jar are lined with tin-foil to within about two inches of the top. These are contained within a wooden box, the interior of which is lined with tin-foil; a piece of wire passes through the foil and the side of the box, and carries on the exterior of the latter a ring, to which should be affixed a chain descending to the table or to the ground; or the chain may be put inside the box, as at C, in contact with the coating of one of the jars.

The ball or knob at the top of every jar is perforated, in order that it may receive one of the brass rods of a system of bars by which the tops of all the jars are connected together; the rods are terminated with brass balls, and one of these, or a ball at the upper extremity of a pillar forming part of the system, or a wire leading therefrom, is presented to the conductor of the electrical machine when the battery is to be charged. This kind of battery was first proposed by Gralath, a German, in 1747; and the manner of charging and of discharging it differs in no respect from the manner of performing the like operations with a single jar.

The quantity of electricity in a jar or battery is directly proportional to the superficies of the coating and to the degree of intensity; and the latter is in the inverse ratio of the thickness of the glass. The particles of vitreous or of positive electricity which, by the machine, are excited in the conductor, and with that on the interior surfaces of the jars, exert, through the glass, attractive powers upon the resinous or negative electricity, which by that attraction are brought from the earth to the exterior surfaces of the jars: this accumulation within the jars continues till the repulsive powers of the particles are great enough to counteract the power of the machine to supply fluid through the conductor: the charge of the battery is then a maximum. The battery is usually furnished with a pith-ball or *quadrant electrometer* [ELECTROMETER], shown in the figure, which indicates by the amount of its divergence the progress of the charge. The discharge is made by means of a bent wire called a *discharging rod*, or by a more convenient form of apparatus known as the *universal discharger*. The power of a battery is estimated by the quantity of metallic wire which it will ignite or melt. The battery, consisting of 100 jars, which was made by Cuthbertson for the museum at Haarlem, and which contained 550 square feet of coating, ignited 655 inches of iron wire $\frac{1}{150}$ inch diameter.

The engraving represents the battery arranged for the deflagration of metallic wires. A conductor is led from the inner coatings of the jars to an insulated arm (*f*) of a discharging apparatus (A), while a second conductor passes from the insulated ball (*b*) to one of the insulated rods of the *universal discharger* (D). The wire to be burnt (W) is attached to a card supported by an insulated stand, and this wire is connected with the other rod of the universal discharger, which connects it by means of a wire with the outer coating of the battery. When the battery is sufficiently charged the lever *i* is withdrawn, when the ball *a* falls down through a hole in the metal arm *f* upon the ball *b*, whereby the circuit is completed, and the charge, passing through the whole conducting arrangement thus formed, restores the equilibrium in an instant; but the wire (W) being thinner than any other part of the discharging wire, there is a very slight delay in the passage of the charge, the consequence of which is that the enormous heating power of the electric fluid has time to act, and the wire (W) is so completely fused as to be dissipated in vapour, a portion of which leaves on the card a stain more or less characteristic of the metal.



The batteries in which electricity is excited by the chemical action of a fluid upon a metal, or of two metals upon one another, are called *Galvanic* or *Voltaic*: they are of various kinds, and will be more conveniently described under GALVANISM.

ELECTRICAL CLOCK. [HOROLOGY.]

ELECTRICAL CONDENSER, a term applied chiefly to such instruments as are employed to collect and render sensible very small quantities of electricity. The principle upon which a condenser of electricity acts may be thus stated: When the electricity of any body is decomposed by being brought near another body which has received from an object in contact with it more than its natural quantity of either kind (vitreous or resinous), the fluid of that kind is repelled from the first body, and that of the opposite kind then disposes the second body to receive a new supply of the former kind from the object with which it is connected. For example, if a thin circular plate of metal, having attached to its circumference a glass handle, by which it may be insulated when held in the hand, be made to receive a small quantity of fluid (suppose it to be vitreous) from the conductor of an electrical machine with which it may be put in connection by a wire; and then a similar piece of metal, connected with the earth by being held in the hand or supported on a pillar of metal, be brought directly under it and so near as almost to touch it, the nearest surfaces of both having been covered with a thin coat of resinous varnish; the electricity of the latter plate will be decomposed, the vitreous portion (in the case supposed) flowing to the earth and the resinous portion being attracted by the fluid in the plate which is connected with the conductor to the upper surface of the other plate. This resinous fluid now attracts more of the vitreous fluid from the conductor to the under surface of the plate in connection with it, and the latter fluid further decomposes the free electricity in the former plate, thus causing in it a new repulsion of the vitreous fluid, and a new attraction of the resinous fluid to its upper surface. The like process continues till an equilibrium is produced between the vitreous fluid supplied by the conductor and the resinous fluid which is drawn from the earth.

If the plate which is connected with the conductor be now removed from thence by means of the glass handle, the fluid in it, having no means of escape, will, on the plate being presented to an electrometer, make its condensed state manifest by producing a greater effect than if the plate, while attached to the conductor, had been unaccompanied by the other plate.

Many different kinds of condensers of electricity have been constructed, and one is represented under ELECTRICITY, COMMON. The condensers of Volta and Cavallo are best known; but, except for some particular purposes, Coulomb's Electrical Torsion Balance [ELECTROMETER] may be advantageously used when it is required to determine the intensity of the fluid in any body.

ELECTRICAL EGG. A glass vessel, ellipsoidal in shape, arranged so that the included air may be exhausted at the air-pump. On sending a stream of electricity through this apparatus various effects are produced, depending on the amount of exhaustion, the force of the electrical current, and the nature of the included gas. When the glass is filled with air the discharge has a white appearance; but as the air is withdrawn, the whiteness diminishes, and at length becomes violet. On increasing the intensity of the discharge, the light increases in brilliancy. When the vessel is partially exhausted, and a current produced by Rhumkorff's apparatus sent through it, the negative ball and the stem which supports the glass, become enveloped in a luminous aureola, formed apparently of several distinct beds of different shades of blue: the positive ball and a portion of its stem are also enveloped in a thin and flocculent aureola of a pinkish hue, while the space between the balls or poles, is filled with a cloud of continuous diffused reddish light. This supposed *stratification*, as it is called, of the electric light, has lately attracted a great deal of attention. It is found to be more decided if, previous to the exhaustion of the air, some vapour of turpentine or pyroligneous acid, alcohol, sulphide of carbon, &c., be introduced. In no case does the light appear to be continuous, but to consist of a succession of discharges, more or less rapid, according to the rate of oscillation of the hammer of the coil. The luminous zones appear to have a double movement of gyration and undulation, which have been regarded by some as an optical illusion, since by causing the hammer to oscillate slowly, the zones appear to be distinct and fixed. The effects can also be produced with a continuous current from a very strong battery, but an intermitting current requires only a single pair, and in this case, any increase in the power of the battery does not appear to increase the effects. M. Gaugain has endeavoured to show that the variations in the light belong to various strata of vapours contained within the glass, and that the electricity assists the arrangement of these vapours into strata.

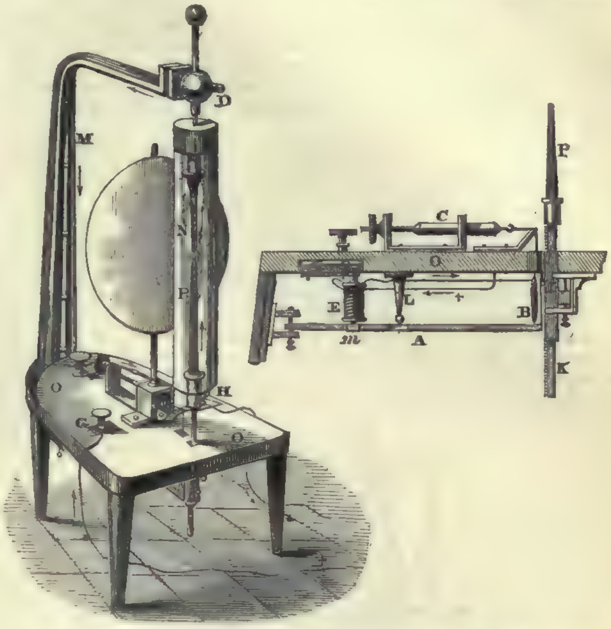
ELECTRICAL IMAGES. Under the article BREATH-FIGURES, will be found a number of curious details respecting the production of electro-graphic images or figures. Lichtenberg's figures are produced by tracing on a cake of resin any marks or figures with the knob of a Leyden jar, charged first positively and then negatively, and projecting on the cake a coloured compound non-conducting powder, such as sulphur and red-lead, triturated together. The powder will render the characters visible; because, in rubbing them up, they become electrified by the friction, the sulphur + and the red-lead —, so that when the powder is blown over the resin, the sulphur is attracted by those parts which are negatively electrified, and the red-lead to those which are positively electrified.

A curious class of electrical images connected with the theory of the distribution of electricity, has been investigated by Professor William Thomson, of Glasgow. The effect of an electrified body on an uninsulated sphere is represented by the image of the electrified body in the sphere. So also, when an electrified body is placed near two uninsulated spheres, an inductive effect is produced, represented by an infinite series of successive images in each sphere. If again a conductor bounded by segments of two spherical surfaces cutting at an angle which is a sub-multiple of two right angles, be electrified by induction, the effect may be represented by a finite number of images placed symmetrically in the circumference of a circle passing through the exciting or inducing body, and cutting the two spherical surfaces at right angles, similarly to the symmetrically arranged images of a kaleidoscope. Mr. Murphy, in his treatise on 'Heat and Electricity,' had previously adopted what he called "the principle of successive influences," for the purpose of obtaining numerical approximations to the state of electrified bodies influencing each other, by calculating the effects of four or five successive acts of influences.

ELECTRICAL LAMP. [ELECTRIC LIGHT.]

ELECTRICAL, or ELECTRIC LIGHT. The most splendid artificial light known is that produced by the current of a powerful voltaic battery between two pencils of hard charcoal, such as that deposited in the retorts of gas works. The charcoal, which is an imperfect conductor, becomes incandescent, and as it is not fusible at any known temperature, the splendour of the light is only limited by the power of the battery. The charcoal is formed into pointed cylinders, three or four inches in length, mounted in metallic holders connected with the ends of the voltaic battery, and the pencils are fixed, so that their points may be easily brought into contact or made to recede from each other as required. When in contact, the current passes between them, and the charcoal becomes eminently luminous. When separated, a splendid flame passes between them, and this flame is not symmetrical with respect to the two poles, for that portion of it next the positive point has the greatest diameter, and as it approaches the negative point, the diameter gradually diminishes. This light can be produced in an exhausted receiver, under water, or in gases which do not support combustion.

This light has been applied by M. Foucault with great effect as a substitute for the lime light in the gas microscope. The apparatus as constructed by M. Dubosc, and called by him a *photo-electric microscope*, contains a self-adjusting apparatus, the object of which is to preserve a nearly uniform brilliancy in the light, notwithstanding the gradual waste of the charcoal. Hitherto the difficulty has been to regulate the light so as to keep the two points at nearly the same distance from each other. The regulators of Messrs. Staite and Petrie in this country, and those of several inventors in France, were intended to produce this result. It will perhaps be sufficient if we here describe the photo-electric apparatus of M. Deleuil. It consists of a tripod of cast iron on which are fixed the two charcoal pencils and the regulator which maintains a constant interval between them. The negative pencil, N, is held by a metal support, the wire of which slides through a hole in the knob, D, with slight friction, so that this pencil once adjusted remains fixed. The positive pencil, P, on the contrary, is so arranged that in proportion as the distance between the pencils tends to increase, the action of the voltaic current causes it to rise. The regulator by which this result is attained is attached to the lower part of the tripod, but is represented on a larger scale in a separate figure, for both of which we are indebted to the 7th edition of M. Ganot's 'Traité elementaire de Physique,' 1857. A is a lever attached at one end to a spiral spring B, so that it can oscillate upon the pivot L through a very small space, the other end being fixed between the points of a vice, capable of being adjusted at pleasure. Now this lever tends to turn in one direction by the action of the spring, B, and in a contrary direction by the action of an electro-magnet, E. At the end of the lever near B is a steel spring, the upper end of which, at I, is engaged in the teeth of a ratched bar, K, on the top of which is a holder of the positive pencil P. Now it is evident that when the current circulates with full force through the wire of the electro-magnet, the latter strongly attacks the iron armature, *m*, attached to the lever, A, whereby the arm of the lever to the right of L descends through a small space, and causes the steel spring, I, to slip into one of the lower teeth of the ratchet bar. This motion does not cause the ratchet bar to descend, since the upper part of the steel spring is curved in such a way as to exert no resistance in descending, but only in ascending. If, however, the distance between the pencils P and N increase, the electrical current becomes weaker, the electro-magnet loses somewhat of its attractive force, and not being able to counteract the action of the spiral spring, B, the latter draws up its end of the lever, and with it the steel spring, I, the effect of which is to raise the bar, K, a quarter of a millemètre. No sooner are the charcoal points brought nearer together, than the current resumes its former intensity, and the electro-magnet acts as before, the steel spring slips into a lower tooth ready to raise the bar when the current becomes enfeebled by the increased distance caused by the wasting away of the charcoal points. The screw at C is for regulating the spiral spring, B. In both figures the direction of the current is indicated by arrows. The charcoal points are preserved from the cooling action of the air by being enclosed in a tube of glass, and a metallic reflector allows the light to be directed and concentrated at any required spot.



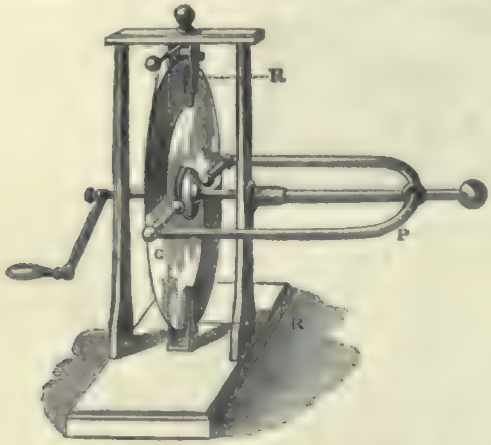
Now that the electric light has been brought under control, it is of course a question of expense, as in the case of electro-motive apparatus, whether we shall employ our coal in smelting the metals which are to be burnt in the voltaic battery, for procuring a source of illumination, or whether our coal may not be more economically employed in generating street gas. This light has been employed in France to give light to the workmen employed at night in excavating the docks at Cherbourg; two sets of apparatus were used, each maintained with one of Bunsen's large batteries of 50 pairs, and these were sufficient to give light to 800 workmen, at the total cost of 14 francs 55 c. for each apparatus. The light has also been employed by night in certain public works in Great Britain.

MM. Fizeau and Foucault have endeavoured to compare the electric light with that of the sun, by means of the chemical effects produced by each source on plates of iodide of silver. Taking the intensity of the solar light at midday at 1000, the electric light from 46 pairs of Bunsen, was represented by 235, while with 80 pairs it was only 238. The intensity of the light, in fact, does not increase with the number of pairs, but with the extent of surface. With three series of 46 pairs each, arranged so that all the positive poles should meet in one, and the negative poles also in one, the effect of which was to triple the amount of surface, the intensity was 385, or more than one-third that of solar light. Bunsen found that 48 pairs not arranged for producing the greatest effect, yielded a light equal to the united effect of 572 wax candles.

The electric light determines the combination of a mixture of chlorine and hydrogen, and acts on chloride of silver in the same manner as solar light. When passed through a prism, a spectrum is produced which differs in some respects from the solar spectrum; but in the case of the electric light, the spectrum varies with the material of which the electrodes are composed.

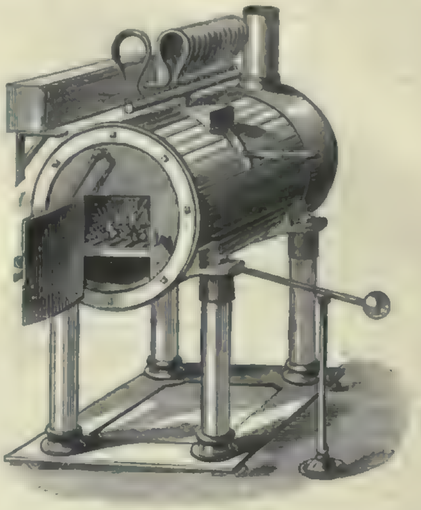
The light produced by the magneto-electric machine [Magneto-Electricity] has lately been applied to the illumination of lighthouses. The South Foreland lighthouse, near Dover, is thus furnished. The lighthouse is placed on a high cliff, and the light is visible at the distance of above 27 miles, and can be seen from the lanterns of the lighthouses of the coast of France.

ELECTRICAL MACHINE. An apparatus for furnishing supplies of electricity. There are two principal forms of this instrument in general use, namely, the *cylinder* and the *plate* machine. The former will be described under Electricity, Common; the latter, in its simplest form, is represented in the annexed figure. It consists of a disc of plate glass, C, moving upon a central horizontal axis with two pair of rubbers or cushions, R, grasping the plate, proceeding from which are flaps of oiled silk, also attached, by means of threads, to fixed points, to prevent the plate from dragging them too much: P, is the prime conductor, insulated by means of a glass stem. When this machine is in good order it furnishes an abundant supply of vitreous electricity. A method of insulating the rubber so as to obtain negative electricity has been contrived by Sir W. Snow Harris, and is described in his 'Rudimentary Electricity.' Plate machines of great power have within the last few years been erected in London; that at the Polytechnic Institution was 7 feet in diameter, and was turned by a small steam engine, while that at the Panopticon, in Leicester Square, was 11 feet in diameter.



A good deal of attention has lately been excited by a new method of mounting plate machines, invented by Winter, of Vienna. There is only one pair of rubbers, and they are large and peculiar in shape; but the most curious feature of the machine is a stem rising vertically from the prime conductor, and carrying at its top a large wooden ring lined within with metal. The effect of this new arrangement is greatly to increase the striking-distance of the sparks; but then it must be borne in mind that the sparks are less frequent than in the ordinary plate machine. This method of mounting does not, *cæteris paribus*, increase the quantity of electricity, but only the size of the sparks and their striking distance. Some of the Edinburgh instrument makers have adopted this method of mounting, but the London makers do not seem disposed to favour it. The reader interested in the subject will find a full account of the method, with figures and measurements, in the second edition of Frick's 'Physikalische Technik,' Braunschweig, 1856, p. 348.

The *Hydro-Electric Machine* is a powerful source of electricity. It originated in 1840, in the observation of a workman who was in charge of a fixed steam-engine at Sighill, near Newcastle. A leak in the cement about the safety valve led to a considerable escape of steam, and the engine-man, in attempting to adjust the weight of the valve, noticed a strong electric spark proceeding from the metal-work of the boiler, and from the boiler itself, if he attempted to touch it while steam was escaping, especially if one hand were immersed in the vapour. Mr. Armstrong (now Sir Charles), of Newcastle, examined the phenomenon, and by means of an insulated brass rod, with a metallic plate at one end and a ball at the other, the former being immersed in the escaping vapour and the latter held near the boiler, sixty or seventy sparks per minute were obtained. Armstrong's hydro-electric machine was based on this result. It consists of a steam-boiler insulated on stout pillars of glass, and of a large number of bent iron tubes, terminating in wooden jets, through which the steam issues with considerable force: projecting from the boiler is a conductor, terminating in a knob, while immediately in front of the jets is a metallic case, containing several rows of points for receiving and carrying off the opposite electricity of the steam, for if it were allowed to return upon the boiler the electrical forces would be neutralised. Faraday has shown that the electricity produced by this machine does not depend merely on the issue of steam through small orifices, nor on any chemical or physical change due to evaporation or condensation, but is the result of the friction of the condensed particles of water which are driven by the steam through the jets, which particles act the part of the glass plate in the common machine, and give out vitreous electricity, while the wooden jets and pipes act as rubbers and give out resinous electricity. In fact the friction of the steam is the source of the electricity; the escaping steam exhibits positive and the boiler negative electricity: it is remarkable that a small quantity of oil or of turpentine in the exit pipe reverses these electrical states. Wood seems to be the best material for the orifice of the jet; ivory one of the worst.



Another electrical apparatus depending on friction is the Electrophorus, and will be described under that head.

Rhumkorff's *Magneto-electric induction coil* is a powerful source of electricity, but the proper place for its description will be found under Magneto-Electricity.

ELECTRICAL, or ELECTRIC TELEGRAPH. [Telegraph.]

ELECTRICAL TIME BALL. [Time Ball.]

ELECTRICITY. A subtle imponderable agent pervading all matter apparently without affecting its volume or temperature, and without displaying its presence in any way when in the latent state; but when excited, its effects may be displayed either in a *sudden*, violent, and destructive manner, or as a less energetic but *continued* force. The remarkable differences in the numerous and varied phenomena of electricity depend chiefly on the modes in which the force is developed, whether by mechanical power or by chemical action, by magnetic or calorific influence, or in certain cases by the animal will. Thus when the force is excited by means of friction, as with the ordinary electrical machine, it is called Common or Frictional Electricity, or in honour of one of the great investigators of this branch of knowledge, Franklinic Electricity. A second modification of electricity is Magnetism, which like common electricity is a polar force, operating on every description of matter, but commonly exhibiting its properties in bars or needles of steel known as *magnets*. The third branch of electrical science is due to chemical action, as when two dissimilar metals are brought into contact in a liquid which acts upon one of them, in which case there is developed an electric current known as Galvanism, or Voltaic Electricity, in honour of the founder and great improver of this branch of science, namely, Galvani and Volta. Fourthly, there is Thermo-Electricity, in which a current is produced by the action of heat upon certain metallic arrangements. Fifthly. Certain fishes, such as the torpedo and the electrical eel, are furnished with an apparatus capable of producing electricity, which for distinction's sake, is termed Animal Electricity. The influence of an electric current on the magnet, or the magnetic relations of the voltaic current, present a large class of important phenomena which are included under Electro-Magnetism, while the electrical phenomena produced by magnetism form the branch of science known as Magneto-Electricity.

Science does not now pretend to explain why electricity is capable of being excited from its neutral condition by any of the means above indicated, any more than the mode of its existence in matter. She does not pretend to decide whether electricity be a material agent, or only a property of matter, or whether, like light and heat, it is supposed to be due to the vibrations of an ether. For the sake of convenience, however, electricity is assumed to be a physical agent, having the properties of an elastic fluid, and hence capable of being held in equilibrium by the mutual action and re-action of antagonistic forces, or of moving in definite directions and forming currents of greater or less intensity. Hence the modes of investigation and the method of classification have had reference to the mechanical sciences, the varied phenomena of electricity being included in one or other of the great divisions Electro-Statics and Electro-Dynamics. In the first of these the electric fluid is regarded in a state of equilibrium or repose, and the phenomena of stationary charges and the laws of excitation and discharge are also studied; while in the second division, which is much the more extensive of the two, the laws of continuous discharge, or of electric currents, are chiefly considered.

Although the electric force is greatly modified by the mode in which it is excited, yet the phenomena are so far related as to suggest the idea of a common principle. Frictional electricity is eminently distinguished by its *tension*, or power of overcoming resistance, which enables it to strike through air from one conducting surface to another, and to discharge itself with great facility from points, whereas the electricity of a powerful voltaic battery, owing to its low tension, has no striking distance either through air or in an exhausted receiver. Frictional electricity passes readily through rarefied and heated air and through flame. In like manner, the voltaic discharge will take place through heated air, as when the charcoal points of the poles of a powerful battery are gradually separated after contact. With a very powerful apparatus the discharge has been thus made to pass through 4 inches of air, and in an exhausted receiver through 6 or 7 inches. Common and voltaic electricity have remarkable heating powers, and in this respect magneto-electricity is not deficient; but neither thermo- nor animal electricity has as yet exhibited heating power. The magnetic powers of all the electricities are strongly marked, especially those of voltaic electricity: all in like manner deflect the magnetic needle, and all have the property of imparting magnetism to steel. Common and voltaic electricity, especially the latter, effect numerous chemical decompositions. Water has been decomposed by the electricity of the torpedo, and also by magnetic action, as well as by thermo-electricity. The shock produced by common and by voltaic electricity becomes painfully exalted when imparted by magneto-electricity. By means of thermo-electricity the limbs of a frog have been convulsed; and the severe shocks given by the torpedo and electrical eel are well known. The spark common to the frictional, voltaic, and magnetic fluids has been obtained from the torpedo. From these and other points of comparison the identity of the five kinds of electricity seems to be made out, the differences of intensity and quantity being sufficient to account for their supposed distinctive qualities. Faraday has further strengthened the belief in their identity by showing that the magnetic force and the chemical action of electricity are in direct proportion to the absolute quantity of the fluid of whatever intensity which passes through the galvanometer. Thus the electric phenomena, connected as they are by well ascertained laws, form the most complete and important addition to the physical sciences that has been made since the time of Newton.

The most important treatise that has been published of late years on all the electrical forces is that by De la Rive, in three large volumes, a translation of which has been published by C. V. Walker. This work contains copious lists of authoritative memoirs; but it should be stated, that the views adopted differ in some important particulars from those of English electricians.

ELECTRICITY, COMMON, FRICTIONAL or FRANKLINIC.

The simplest and most usual mode of producing electricity is by friction. When any two substances are rubbed against each other briskly it is always produced; but it is only a particular description of bodies called *non-conductors* that retain it after it is thus produced so as to exhibit its primary effects of *attraction* and *repulsion*.

The production of electricity may be observed in a very familiar manner thus: Tear up a piece of paper into small fragments, and place them on a table; then take a stick of sealing-wax, and rub it briskly with a piece of flannel, or against the sleeve of a cloth coat, and immediately after hold it near the fragments of paper; these small pieces will be soon observed to be agitated and the smaller to fly with considerable velocity to the wax, to which having adhered for some time, some will suddenly jump off, others which have touched the stick edgeways will dangle from it for a considerable time, and then fall off by their own gravitation when the electrical force has sufficiently subsided. It was by observing that amber produced similar effects after friction to those we have described that electricity obtained its name (ἤλεκτρον, amber).

Glass is now more commonly employed to produce electricity than wax or gum; and there is a striking difference in the kind of electricity then generated, which we shall afterwards notice more at length. These bodies are non-conductors, as they manifestly retain their electricity beyond the moment of its production, and they are *isolators* or *insulators*, because a conducting substance will also retain its electricity when communication with the earth, or with other conducting substances, is cut off by means of non-conducting supports or envelopes.

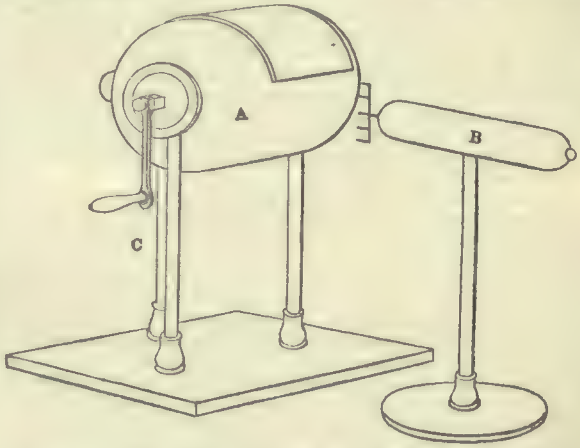
Water is a conductor of electricity; for if we immerse a conducting insulated and electrised substance in water, it will be completely deprived of its electrical properties. Perfectly dry airs or gases, on the other hand, are non-conductors; for if not, none of the phenomena mentioned could have been observed, as the experiments are not made in vacuo. We are not aware that it has yet been established whether the vapours of all substances are conductors (or all the gases non-conductors). Aqueous vapour certainly is a conductor; and therefore, when the air is impregnated with moisture, it is difficult to perform any electrical experiments which require duration. [Electric.]

Hence a conductor constitutes a channel by which the electricity produced on a non-conductor will escape, and a non-conductor constitutes an insulator by which the electricity communicated to a conductor may be retained. Thus, if we place an electrified glass tube on a tin stand, the metals being conductors, the electricity will be gradually dissipated; on the contrary, if we place an electrised tin cylinder on a glass support in dry air, the electricity will be retained for a long time.

Nevertheless it is far from improbable that this is a question only of degree; that all substances are conductors; and that the usual terms conductor and non-conductor strictly mean quick conductor and slow conductor.

When an electrised body is brought near the skin where the power of touch is delicate, a sensation is produced which has been compared to that produced by the touch of a cobweb; but instruments founded on the laws of electric action have been constructed, which indicate the presence of electricity in its most feeble state, and measure its tension. [Electrometer.]

Previous to our study of the properties of electricity, on which the construction of the best machines for procuring it in large quantities depends, it will be useful to describe a simple apparatus, and one easily constructed or procured, by which we may learn the first laws of electrical action.



A represents a glass cylinder of which the axis is supported on a frame, and which is pressed against by a cushion stuffed with horsehair, and covered by an amalgam of zinc, tin, and mercury ground up with lard and spread over its surface; this cushion is mounted on a glass rod C, but attached to the cushion is a metal chain communicating with the table or the ground. At one extremity of the axis of the cylinder is attached a handle by which it may be rapidly turned round, and the friction which is generated against the cushion will produce electricity on the surface of the glass, to guard which against the action of the moisture of the air, the upper side of the cylinder may be lapped over by a piece of glazed taffeta in the direction of the rotary motion of the cylinder. B is a long narrow and hollow metallic cylinder standing on a glass support, and having at the extremity near A a small cross bar garnished with points or teeth presented towards the cylinder. B is called the *prime conductor* in this apparatus, or *cylinder electrical machine* as it is called. When the cylinder A is turned briskly round, the motion will be accompanied by a crackling noise, and in the dark, streams of light of a yellowish or bluish hue will be perceived directed to the several points on the projecting bar of the conductor. B may be thus *charged* with electricity, and when removed from the presence of the cylinder (taking it away by its insulating support), it will retain its electrical properties (the longer as the air is more free from moisture), and will by simple contact communicate a portion of its electricity to another isolated conducting substance, or be discharged by touching one not isolated: if, with a feeble charge, it be touched by the finger, a sensation like the pricking of a needle will be felt, accompanied by a faint spark apparently penetrating the fingers.

It is useful to cover the glass supports at their points of contact with gum-lac, which is an excellent insulator.

Glass plates are now in more general use than cylinders for the production of electricity by friction. [Electrical Machine.] Perhaps the most perfect apparatus for producing electricity, and also measuring its quantity, is that employed by Sir W. Snow Harris, and described in his 'Rudimentary Treatise on Electricity.'

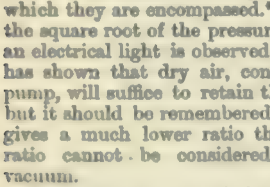
We shall now observe, as our first phenomenon, that neither the cylinder which has generated and given out electricity, nor the conductor which has acquired it, exhibits the least alteration of weight, nor will the greatest possible accumulation of electricity produce the least perceptible alteration in this way. Those who suppose that electricity is a distinct species of matter, an all-pervading fluid, have therefore denominated it *imponderable*. Facts do not, however, authorise us yet to take this view of it, or to regard it as essentially different from the forces which the molecules of matter exercise, which, though neutralised for external bodies when these molecules are in positions of equilibrium or stability relative to their mean places, may become sensible by impressed forces, such as friction, which would alter the position of their poles, or by sudden concussion forcibly altering their relative situations. There is a convenience of language, however, in speaking of electricity as a *fluid*, which can lead to no error by its adoption until the phenomena of molecular action have been more studied, and the views of Mosotti and many other natural philosophers with respect to the identity of these forces better established. [ATTRACTION.] Adopting, therefore, this hypothesis, the sense in which we speak of its quantity, its accumulation, its density, or its partition between bodies, may be readily translated into the hypothesis founded on the views of molecular action if we should find any occasion for it.

The next phenomenon to be noticed is the limit to the quantity of electricity which we can communicate to a perfect conductor. If, from different sources of electricity, we charge a metallic ball, and so continue to charge, we shall find that there is a limit beyond which we cannot communicate more; for on attempting so to do, the ball will discharge itself through the air into the nearest conducting body, when a spark, describing apparently a zigzag course, will be observed, the colour of the light being dependent on the medium which it traverses. This spark travels with immense velocity (as will be noticed more particularly hereafter), and is accompanied by a very audible sound; and if received by the body of a man or animal, it produces through a part or the whole of the system an instantaneous muscular contraction, which may be rendered sufficiently strong to cause death, but in more moderation has been used in some diseases, such as deafness, though its use has become by no means general, and indeed the curative effect is very doubtful.

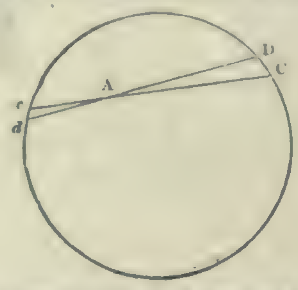
Two points determine this limit, or fix the charge of which a perfect conductor is susceptible. The first is the extent of its surface; for if two bodies have similar figures, the quantities of electricity of which they are capable are proportional, not to their solid content or weight, but to their surfaces; that is, to the square of their linear dimensions. The second is the pressure of the non-conducting medium by which they are encompassed.* The quantity of electricity is then as the square root of the pressure. When placed in an artificial vacuum, an electrical light is observed along the sides of the machine. Harris has shown that dry air, considerably rarefied by the action of the pump, will suffice to retain the electricity of a body for a long time; but it should be remembered that the square root of two quantities gives a much lower ratio than the quantities themselves; and this ratio cannot be considered very small in any artificially-formed vacuum.

That the quantities of electricity should follow the law of proportionality to the surfaces, and not to the content or weight of the body, will not excite surprise when it is stated that no developed electricity exists within a body, at least to any appreciable depth below its surface. This fact has been repeatedly confirmed by experiment; and in consequence of this law we see the advantage of using a long cylindrical form for a conductor, and perceive the proportions in which the partition of electricity takes place when several similar conductors communicate.

We come now to the third and very important phenomenon of the mutual repulsion of the different parts of developed electricity: these parts repel each other with forces which vary inversely as the square of the distance. We may easily witness this repulsion in the following familiar manner. Take a small well-dried ball of elder-pith, and suspend it from the hand by a fine silk thread, which is a good non-conductor; then bring it near the conductor of an electrical machine, or to a body to which this conductor has communicated electricity. The ball will at first be attracted to this body; but when it has touched it and shared a small portion of its electricity, it will be repelled from it and will stretch the string by which it is suspended in a slanting direction, until the obliquity is sufficiently great for its own gravity and the tension of the string to counterpoise the repulsion of the electricity on the conductor. Let two pith balls be suspended by parallel strings so as to touch each other, as A, B, and if a portion of electricity be communicated to them by temporary contact with a body already charged, the strings will diverge in consequence of the mutual repulsion, and the balls will come into the positions *a*, *b*, where, notwithstanding their gravitation, they will remain a considerable time, if the air be very free from moisture. They will be observed gradually to close in towards each other as they lose their electricity from the contact of the surrounding medium.



That the law of force in this case is, as in gravitation, expressed by the inverse square of the distance, was satisfactorily demonstrated by Coulomb by means of his torsion balance, the principle of which we have before explained [ELASTICITY], and has been confirmed by Harris's experiments: and a remarkable fact arises from it, namely, if the electrised pith-ball A be placed any where within the concavity of a spherical shell, it will not be moved in any direction by the repulsion of the electricity on the surface of the shell; for the electricity being then uniformly distributed, the intensity of the force of any small portion DC is at its extent, or proportional to the square of the arc DC, and is therefore destroyed by the action of an opposite portion *dc*, cut off by a conical surface having A as vertex, and DC as base; for $DC^2 : dc^2 :: DA^2 : cA^2$, that is, what the portion gains in extent it loses in its distance from A. This law was first demonstrated by Newton ('Principia,' book 12), and it was afterwards shown by other analysts, that for no other law of force but that stated could the same mutual destruction of forces occur (Laplace, 'Mécanique Céleste,' tom. i., liv. 2; Murphy's 'Electricity,' chap. iii.); and Poisson, from other considerations which we shall afterwards notice, made this condition, for a body of any figure, the ground of his calculations on the distribution of electricity over the surfaces of bodies.



When electricity is produced, as above described, and a conductor charged, if the conductor be removed, and another conductor replace it, the latter will become charged by repeating the operation: thus the cylinder, and indeed every substance properly mounted, is an inexhaustible source of electricity.

We have supposed the cushion by which the cylinder is rubbed to be in communication with the ground by means of a conductor; but if two substances both isolated be electrised by friction, and when separated the electricities belonging to each surface be examined, we find the following results:—

Let two insulated pith-balls, A and B, as before, be electrised by communication with one of the surfaces, and two other balls *a* *b* in like manner electrised by the other surface. Then when A is presented to B, or *a* to *b*, repulsion takes place as before described; but when A is presented to *a*, or B to *b*, they will attract each other; and if A, *a* have equal charges from the different surfaces which have been rubbed against each other, when contact takes place between A and *a*, all signs of developed electricity will depart from each, and the bodies will take their natural positions, neither attracting nor repelling each other; but if A has a greater electrical charge than *a*, a surplus of the electricity of A will remain, and will be partly communicated to *a* when a consequent repulsion arises.

The same results would occur if two machines were used, in one of which the cylinder is glass, and in the other resin or a gummed substance: the pith-ball which receives its electricity from the glass cylinder will attract that which has been in communication with the other machine.

Hence arise the terms *vitreous* electricity and *resinous* electricity, or, as they are also called, *positive* electricity and *negative;* for whatever two substances they may be which are rubbed together when electricity is produced, it will be found positive on one substance and negative on the other, even if the substances are of the same nature; for instance, both glass. [It is necessary, however, that the two surfaces be in different physical states, such as one rough and the other smooth, or heat, not electricity, will be the result of the friction.]

The phenomenon above noticed may be then announced as follows: "Like electricities mutually repel, unlike mutually attract;" and the law of force between particle and particle is in both cases the inverse square of the distance.

Moreover, we have seen that the addition of quantities of unlike electricities is similar to the addition of quantities with unlike signs in algebra: when equal the sum is zero, when unequal it is the excess, and of the same name as the greater charge.

Franklin's theory makes only one electric fluid in excess above its natural state in bodies positively electrised, and in defect in those said to be negatively electrised. Epinus, and most of the continental philosophers after him, suppose the existence of two distinct electrical fluids, the particles of each of which repel those of the same kind, but attract those of the contrary, and therefore the opposite electricities always seek combination or neutralisation, so that in natural bodies the two fluids exist in equal quantity, by which the presence of neither is indicated. Mosotti has in some degree revived the theory of Franklin in his memoir on the forces which determine the state of bodies. [ATTRACTION.] We adopt at present the theory of two fluids, but all the phenomena may be readily expressed also on Franklin's theory.

---

* This idea of pressure has been considerably modified since the adoption of Faraday's views, which will be stated further on.

The pressure of the electricity on the surrounding medium, when the body is perfectly conducting, determines the direction of the motion under the influence of foreign electrised or non-electrised substances, which, by rendering this pressure unequal on the different parts of the surface, produce motion by the unequal reaction of the medium. But imperfectly conducting bodies have in themselves a certain retentive or coercive force, and the electrical particles, instead of then freely obeying the external impressed force by a corresponding law of arrangement or accumulation amongst themselves, communicate the forces impressed to the particles of matter by which they are restrained. In imperfect conductors the force is partially exercised in each of these ways. The circumstances of the motions of electrised substances therefore vary with their conducting faculty.

We can now understand the mode in which light substances are attracted to a stick of sealing-wax which has been made electrical by friction; the electricity of the wax is in this case negative; and when brought near a small piece of paper, which is a conductor, it acts upon the neutral fluid of the paper, attracting some of its positive electricity to the side next it, and forcing the negative to the farther surface, which, being in communication with the ground or a conductor, is carried off; so that the paper is thus *by influence* made positively electrical, which, being of a contrary kind to that of the wax, is attracted by it, and therefore the paper flies to the wax, and having touched it communicates its positive electricity to it, thereby neutralising a portion of its free fluid; after which it shares a part of the surplus of negative electricity remaining on the wax, when it is of course repelled; and if it become neutral by again touching the ground, and the electrical force has sufficient energy, it will again fly to the wax and the same results will be repeated.

When a body is of an irregular figure, and is electrised, the electricity of its surface will be differently accumulated at the different parts, projecting points having the most, and portions of small curvature the least in convex surfaces; and it is a mathematical problem of considerable difficulty in some cases "to find the law of the distribution of free electricity on the surface of a perfectly conducting body of a given form." The datum for the solution is, that the whole action of the electric envelope on any point interior to the body is zero: we have shown that it would be so in the case of a sphere by a uniform distribution on the surface: but in other bodies this distribution cannot be uniform to produce the same effect. The next case in the order of simplicity is the spheroid, or more generally the ellipsoid, for a spheroidal shell, bounded by two similar and concentric spheroidal surfaces, and attracting by the law of the inverse square of the distance, will exercise no action on an internal point; hence the accumulation of electricity on the surface of a spheroid at any point is proportional to the normal breadth of the stratum at that point, which it may be easily proved is proportional to the perpendicular drawn from the centre on the tangent plane, or inversely as the diameter parallel to the tangent at that point.

Hence we see why the accumulation of electricity at points is so great, which are therefore part of the armature of prime conductors; for if we conceive the axis minor of an ellipse to diminish indefinitely, while the axis major remains invariable, the breadth of the spheroid generated will be correspondingly diminished while the length remains the same, and ultimately it will approximate to the form of a needle pointed at the extremities of its axis major, the breadth of the electricity at the point is then to that at the middle of the needle as the length of the needle is to its greatest breadth. Now, in consequence of the law of force being the inverse square of the distance, we find the pressure against the air is as the square of the accumulation, and consequently is very much greater at either extremity of the needle than at or towards the middle; and therefore, on being overcharged, the electrical spark is given from the extremity, when not otherwise determined by the influence of external bodies.

Moreover, when several conducting bodies, some or all of which are electrised, are placed near each other, a new distribution of electricity takes place on their surfaces, caused by the decomposition of the neutral fluid of each by the action of the extraneous substances: thus, the principle for calculating the distribution in this case on every body is to suppose it such that the total action on any point within each of the conductors shall be zero; for if not, the neutral fluid at that point would be decomposed, and the separated fluids proceeding to the surface of the body would alter the distribution. When the distribution is ascertained, then the motions of the bodies may be calculated according to the laws of dynamics, the pressure against the surrounding medium being as the square of the accumulation.

Two spheres placed in contact and electrised will have the point of contact neutral. This result of theory (founded on the principles above detailed), with many others, has been fully confirmed by experiment. Those who wish to follow up the mathematical principle here noticed, may see Poisson's 'Memoirs on Electricity' ('Mémoires de l'Institut'), and an English treatise expressly on this subject by Mr. Murphy of Cambridge. We may however here introduce a few popular details on the subject, chiefly with reference to the distribution of electricity or the densities of the electric fluid in different bodies placed so as to act electrically upon one another, or in different parts of the same body when the latter had been subject to the electrical influence of another body.

When a body possesses equal quantities of the opposite kinds of electricity, the fluid may be conceived to be uniformly diffused through it; and two such bodies being placed in contact, will produce no effect on each other, because the attractions existing between the particles of the unlike fluids are counteracted by the equal repulsions between the particles of the like fluids. But if a body acquire by any means an excess of either the positive or negative fluid, a mutual action will take place between this body and any other in its vicinity, the fluids in the latter being previously in equilibrio or not.

It was early found that two electrified spheres, equal in magnitude, but of which one was solid and the other a thin shell, acquired precisely equal quantities of the electric fluid; and hence it was inferred that such acquired fluid existed only upon or near the surface of an electrified body. The experiments also of Franklin on a charged Leyden jar with interior and exterior coatings, which could be removed and replaced at pleasure; and those of Coulomb, in which, by a proper apparatus, electricity was drawn from the surface of a charged body when none could be obtained from the bottoms or sides of holes sunk in it to certain depths, sufficiently prove that the electric fluid exists in a stratum on the surface or rather within the body at an infinitely small distance from the surface.

If a sphere have uniformly diffused over its surface a charge of either kind of electricity, and there be placed in contact with it a sphere of equal magnitude in which the electric fluids are in equilibrio, a mutual action between the spheres will take place; the effect of which will be that the fluid particles of opposite kinds in both spheres will have their equilibrium disturbed, and equal quantities of both kinds will flow to the surface of each: the density of the fluid, or the thickness of the stratum at either surface, being different in the circumferences of circles at different distances from the point of contact.

The investigation, by mathematical analysis, of the laws of the distribution of electricity being too extensive for this place, it must suffice to state the results of some of the experiments made by Coulomb on that subject.

When a sphere, charged as above supposed, is placed in contact with another in which the fluids are in equilibrio, whatever be the ratio between the diameters of the spheres, the density or the thickness of the stratum of fluid on each is, at the point of contact, equal to zero; and, at the opposite extremity of the diameter passing through that point, the density is the greatest. Representing the density opposite to the point of contact by unity, the results of the experiments with two equal spheres show that, in an indefinitely narrow zone at thirty degrees from the point of contact on each, the density may be represented by 0·2; at sixty degrees from that point, by 0·76; and at ninety degrees, by 0·95: it is found also that the mean density on each sphere is represented by 0·79.

When two spheres, in the circumstances just mentioned, but having the diameter of one double the diameter of the other, are placed in contact, the experiments of Coulomb show that, on the smaller sphere, the density opposite to the point of contact is, to the density at ninety degrees from that point, as 1 to 0·75; and at sixty degrees, as 1 to 0·44: they also show that, at ninety degrees from the point of contact, the density on the smaller sphere is to the density on the larger as 1 to 0·8; and that the greatest density on the smaller sphere is to the mean density on the greater as 1 to 0·64. When the diameters of the spheres were to one another as 4 to 1, it was found that the greatest density on the smaller sphere was to the mean density on the greater as 1 to 0·43.

If two spheres which have been placed in contact are subsequently removed beyond each other's influence, the density of the fluid at the surface of each becomes uniform; but on the larger sphere the density is always greater than on the smaller sphere. From Coulomb's experiments it is found that when the diameters of the spheres are as 2 to 1 the densities are as 1·08 to 1; and when the radii are as 4 to 1 the densities are as 1·3 to 1. That philosopher infers also from his experiments, that in no case can the ratio of the densities on two unequal spheres be greater than that of 2 to 1.

When an electrified globe and a circular disc were placed in contact, Coulomb found that the quantities of fluid on them were directly proportional to their entire surfaces. The distribution of electricity on the surface of a spheroid has already been noticed.

When electricity is generated by the friction of two substances, one acquires positive, the other negative electricity, but it is difficult to judge *à priori*, from the nature of the substances employed, the character of the electricity which each will take; and though most treatises contain tables of substances in which each is positive to that which precedes and negative to the succeeding, yet the nature of the electricity is so liable to alteration, from very minute circumstances of the friction, that it is better, even in each case, to try direct experiment. The friction produced by liquids also produces electricity, the electric light, when a barometer well freed from air is first filled with mercury, having been remarked from the earliest dates of the use of that instrument [BAROMETER]; and we have seen in the case of the hydro-electric machine [ELECTRICAL MACHINE], that water in the form of small drops acts as the *rubber*. So also when a current of air is directed against a plate of glass, the latter will acquire positive electricity, and therefore the air negative, and the rapid agitation of a piece of silk in the air communicates to the latter positive electricity while the silk acquires negative.

The difference of temperature of a substance often determines the species of electricity which it acquires by friction. Generally an increase of temperature disposes to negative electricity, and polish or smoothness to positive; pressure on many crystals will produce opposite electricities, as will also heat (as in tourmaline), and even the slight adherence which a piece of glazed taffeta would have to an isolated metallic plate which it covers is sufficient to give the plate negative electricity, which is the more remarkable from the fact that the friction of the two would have made the taffeta negative and the plate positive.

Moreover, both the electricities are produced in most of the chemical compositions and decompositions, in the sudden fracture of substances, in evaporations, &c.; and the higher couches of the air are in a state of positive electricity when unoccupied by clouds, which are found indifferently charged with either. [ELECTRICITY, ATMOSPHERIC.]

When a body is positively electrised, we can procure the negative electrisation of another conducting substance by the influence of the former on the neutral electricity of the latter: this is what is understood by *electrical induction*. Let the conductor be placed in the vicinity of the influencing body, but not so close as to receive any positive electricity by sparks or other direct communication. The natural electricities of the conductor will be then separated by the influence of the positively electrised body, towards which the negative electricity must be attracted and the positive repelled; the part of the conductor nearest the influencing body must therefore be covered with negative electricity, and that more remote with positive. If, now, this end of the conductor be made to communicate with the ground, the positive electricity will escape into this great reservoir, and moreover sufficient negative electricity will be communicated from the ground to the conductor to render the point of contact neutral: thus the conductor acquires a double charge of negative electricity, and when isolated will be found negatively electrised after it has been removed from the vicinity of the isolating body.

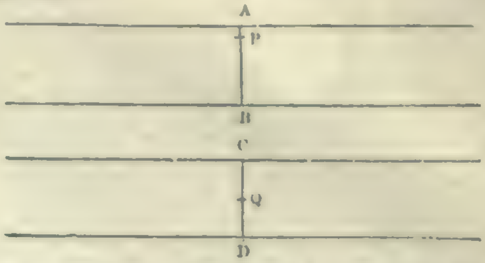
The effects of influence or induction, as above described, may be easily observed in the following manner: Place a long and narrow insulated conducting cylinder before a body strongly electrised, and from different equi-distant points of the cylinder suspend pairs of pith-balls by cotton threads, which will acquire the electricities of the parts of the cylinder with which they are connected. We shall observe a considerable divergence in the pair suspended nearest the influencing body, because they are strongly charged with an electricity of a contrary nature to that of the body: going along the cylinder, the divergence diminishes, and at a point not as remote as the middle of the cylinder there will be no divergence. Beyond this neutral line the cylinder has an electricity of the same kind as the influencing body, increasing in intensity towards its farthest extremity, and therefore the strings commence to diverge more and more as we approach that end. In making this experiment a single pair of pith-balls moved along the cylinder will be sufficient if we secure them from the direct influence of the body by a piece of glass interposed near them.

This is the direct influence which the electrised body has on a neutral body, very different from the methods of developing electricity by excitation and communication already referred to. Here is a charged body exerting an inductive action on an insulated cylinder, and developing on it not merely one electricity of an opposite kind to itself, but equal quantities of the two electricities. We shall return to the phenomena of induction presently, in order to point out some of the results obtained by Faraday and the modern electricians: but having now seen the action of an electrised on a neutral body, we may remark that the neutral body must again re-act on the original body, sensibly decomposing its electricity if it be a conductor; and thus the true arrangement of the electricity, in two surfaces influencing each other, although instantaneously effected, may be regarded as the final effect of a succession of direct and reflected influences between the bodies. [ELECTRICAL IMAGES.] This principle has been shown by Mr. Murphy materially to facilitate the actual calculation of the distribution of electricity on two electrised surfaces in presence of each other.

The effect of the influence of a near electrised cloud has been felt by several persons, among others by the writer; and in many cases fatal results have followed, not from the direct discharge of the electricity, or, as it is called, the *lightning*, but from the sudden re-union of the electricities which had been separated by influence, and which, upon the discharge of the cloud, is effected by means of a corresponding electric charge brought through the body from the ground.

From the power of separation of the neutral fluid in bodies at a distance which is exercised by electricity, an easy means has presented itself by which a much greater quantity of electricity may be collected upon a conducting plate than that which could be directly communicated by a conductor. We shall therefore now endeavour to explain the principle of the condenser, which we think is very inaccurately stated in Biot's 'Physique,' in which the subject of electricity is treated, generally speaking, in a very luminous manner.

The following investigation the author of this article gives, on his own responsibility, with the desire of placing the power of the condenser on its true basis:—



Suppose two equal conducting plates, of which the axes are A B, C D to communicate respectively at A and D with known sources of electricity, and have their opposite faces B, C, near to each other and parallel, the whole being surrounded by a non-conducting medium, the known sources of electricity communicate quantities E, E′ of electricity to the bases B, D, and the mutual influences of the system generate other quantities X, X′ on the second bases B, C, these quantities are dependent on E, E′, on A B, C D, which for simplicity we shall suppose both equal to c, and on the mutual distance B, C of the plates, which we shall call a. Our problem is to find X and X′ from these data.

Consider the total action on a point P, taken anywhere within the first plate and on its axis; this must be equal to zero, in order that the neutral electricity at that point may not be further decomposed. Let P B $= z$.

The action arising from the base A and the adjoining portion of the sides of the plate included between A and a parallel drawn through P is $\mathrm{E}\,f\,(c-z)$; the form of the function f is unknown, since it depends on the law of the distribution of the fluid at the different parts of the base and sides.

Similarly, the action arising from the base $\mathrm{B} = \mathrm{X}\,f\,(z)$
.. .. $\mathrm{C} = \mathrm{X}'\,f\,(a+z)$
.. .. $\mathrm{D} = \mathrm{E}'\,f\,(a+c+z)$.

Our first equation of condition must therefore be—

$$\mathrm{X}\,f\,(z) + \mathrm{X}'\,f\,(a+z) - \mathrm{E}\,f\,(c-z) + \mathrm{E}'\,f\,(a+c+z) = o \;\ldots\ldots\; (1);$$

and if we consider in precisely the same way the equilibrium of a point Q within the second plate and in its axis, we obtain (putting C Q $= z'$)—

$$\mathrm{X}'\,f\,(z') + \mathrm{X}\,f\,(a+z') - \mathrm{E}'\,f\,(c-z') + \mathrm{E}\,f\,(a+c+z') = o \;\ldots\ldots\; (2).$$

The equations (1) and (2) must hold true for all values of z and z' between o and c, and they serve to determine the form of the function and the values of X, X′.

If the bases were infinite, $f\,(z)$ would be constant. ('Principia,' book xiv.)

Now $f\,(z) = f\,(o) + f'\,(o)\,.\,z + f''\,(o)\,.\,\frac{z^2}{1.2} +$ &c. by Maclaurin's Theorem $:= f\,(o)\left\{1 + n\,\frac{z}{c}\right\}$ nearly; for z being very small, we reject the powers higher than the first, and put $\frac{n}{c}$ for abridgment, instead of $\frac{f'\,(o)}{f\,(o)}$; c is introduced for homogeneity.

We may observe that n is necessarily a very small fraction in the actual case; for it depends on $\frac{c}{\mathrm{R}}$, R being the linear dimension of the base, and it vanishes when R is infinite.

The equations may be thus simplified; and dividing them by $f(o)$ they become—

$$\mathrm{X} + \mathrm{X}'\left(1 + \frac{n\,a}{c}\right) - \mathrm{E}\,(1+n) + \mathrm{E}'\left(1 + \frac{n\,a}{c} + n\right) + \frac{n\,z}{c}\,(\mathrm{X} + \mathrm{X}' + \mathrm{E} + \mathrm{E}') = o \;\ldots.\; (3)$$

$$\mathrm{X}' + \mathrm{X}\left(1 + \frac{n\,a}{c}\right) - \mathrm{E}'\,(1+n) + \mathrm{E}\left(1 + \frac{n\,a}{c} + n\right) + \frac{n\,z'}{c}\,(\mathrm{X} + \mathrm{X}' + \mathrm{E} + \mathrm{E}') = o \;\ldots.\; (4).$$

Hence by subtraction and dividing by $\frac{n\,a}{c}$, we obtain—

$$\mathrm{X}' + \mathrm{X} + (\mathrm{E}' - \mathrm{E})\left(1 + \frac{2\,c}{n\,a} + \frac{2\,c}{a}\right) + \frac{z - z'}{a}\,(\mathrm{X} + \mathrm{X}' + \mathrm{E} + \mathrm{E}') = o \;\ldots\; (5).$$

Since $z - z'$ may be positive, negative, or zero, and yet this equation always true, we must have separately—

$$\left.\begin{array}{l} \mathrm{X}' - \mathrm{X} = (\mathrm{E} - \mathrm{E}')\left(1 + \frac{2\,c}{n\,a} + \frac{2\,c}{a}\right) \\ \mathrm{X}' + \mathrm{X} = -(\mathrm{E} + \mathrm{E}') \end{array}\right\}\begin{array}{l} \ldots.\; (6) \\ \ldots.\; (7) \end{array}$$

It will be useful to make a few remarks before proceeding further

The expression which we have put for the action of the plane C on F in equation (3) is in reality the action not only of that plane, but also of the side of the prism or cylinder, of which the base is C and altitude CF; and a similar remark applies to the action of the plane D: therefore the total action given in that equation is too great by twice the action of the side of the prism or cylinder included between the plates B and C. For the same reasons we have a like excess in the equation (4); wherefore we have subtracted these equations, when that excess disappears; whereas, if we had added them, an error would arise, small with respect to X and X', but comparable to $E + E'$.

Also, from equation (7), the apparatus would be discharged by making the two plates communicate.

In the actual case the lower plate communicates with the ground; therefore $E' = o$.

Adding now the two equations, we find—

$$X' = \frac{cE}{a}\left(1 + \frac{1}{n}\right),$$

and subtracting—

$$X = -\frac{cE}{a}\left(1 + \frac{1}{n} + \frac{a}{c}\right).$$

n is a very small quantity and negative, since the attractive force diminishes as the point acted on becomes more remote. Hence X is very great and positive compared with E, and it follows:

First, that the greater the extent of the plates, the less n will be, being zero when that extent is infinite; therefore the power of the condenser is increased by the extent of the surfaces being enlarged.

Second, that another source of increase of the condensing power is the diminution of a, the space occupied by the non-conducting medium interposed between the parallel conducting plates.

These results are perfectly accordant with experience.

In practice, the conducting plates are generally separated by a plate of glass or a cover of varnish, the latter being used when the electrical charge is feeble; for the attractive forces of the two opposite electricities $X\ X'$ would be too powerful for such an obstacle if E were great, and the electricities would penetrate it and unite; but in chemical operations, where the electricity developed is of weak tension, the diminution of a is of great advantage, the quantity of electricity acquired by the plates becoming very sensible to the electrometer. [ELECTROMETER.]

The Leyden jar is an instrument founded on these principles. A glass bottle is coated within and without with tin-foil. The conductor of an electrical machine communicates with the foil on the inside by means of a metallic chain, while the outside is in communication with the ground. The opposite electricities are therefore accumulated on the internal and external sides of the glass: hence a flash and a powerful shock is produced, when the two fluids combine, by touching the outside foil with one hand while the conductor or chain communicating with the inside is touched by the other.

It was ascertained by Cavendish that the quantity of electricity produced in the Leyden jar, with given surfaces, was inversely proportional to the breadth of the glass; this completely corresponds with the results which we have above obtained by theoretical considerations.

There seems little doubt, from the experiments of Wollaston, that much of the electricity produced by the common machine is attributable to chemical action; for the best amalgam to use with the rubber is that which oxidises most readily, such as tin and zinc; and scarcely any quantity of electricity is produced if, by the nature of the amalgam, there is no sensible oxidation, or if we envelope the apparatus in a medium which will not communicate oxygen, as carbonic acid gas. As the quantity taken by the conductors is proportional, *cœteris paribus*, to their surfaces, it is usual to employ several narrow cylindrical conductors placed parallel to each other; the total surface in this case being the same as that of a single cylinder of the same length, and of which the radius would be the sum of all their radii.

The electrophorus is founded on a principle nearly similar to that of the condenser; but in this case it is the non-isolated body which acquires electricity by the influence of that which is isolated.

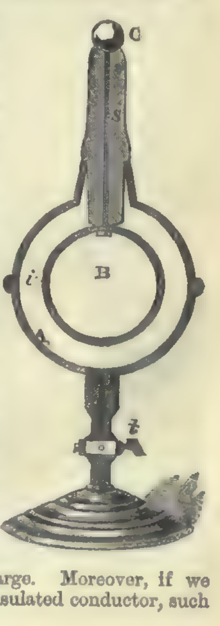
It should be observed, that the non-conducting plates employed in the condenser and Leyden jar have a certain retentive power on the electricity, and which is of the same origin as its non-conducting faculty: hence it will happen generally in experiments that the whole of the electricity will not be discharged at once, when the opposite electricities of the two plates are made to communicate by a conductor, and frequently not after several repetitions. The same principle of the separation of the neutral electricity of remote bodies by influence is observed in the electrical machines which have been at different times constructed. [ELECTRICAL BATTERY; ELECTRICAL MACHINE.]

In the best conducted experiments there will be a loss of electricity, arising either from the hygrometric state of the atmosphere, or the imperfect insulation of the supporters employed. When, for instance, the moist particles of vapour floating in the air come in contact with the conductor of an electrical machine, they acquire by their own conducting power a small portion of the electricity developed in the conductor; being similarly electrised they are repelled; and new particles of moisture arising, repeat the same process of exhaustion, each tiny robber carrying away as much electricity, not as it can hold, but as it may hold without being itself held. The quantity thus lost in a small given time is proportional to the whole charge, and therefore the latter must diminish in a geometrical progression when the time increases in arithmetical.

The reviser of the above masterly article (which was furnished by the late Robert Murphy to the 'Penny Cyclopædia') has been unwilling to do more than modernise a few of the terms and erase a few lines on subjects which the present state of electrical science required to be treated of at greater length under separate heads. It is now proposed to add some brief particulars of the admirable labours of Faraday in this branch of science, referring those who desire further information to his numerous papers published in the 'Philosophical Transactions' during the last twenty years, but collected into three volumes entitled 'Electrical Researches,' 1838—1858.

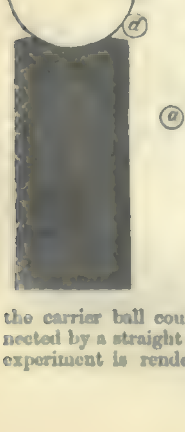
The theory of electrisation by influence did not take into account the medium which separated the excited body from the one acted on. It was said, for example, that an electrified cloud would throw a corresponding portion of the earth's surface into a negative state independently of, or at any rate without reference to, the interposed air, which was supposed to remain passive during the action of the force, and then to oppose by its non-conductibility the union of the opposite electricities. The experiments of Faraday, however, have led to the conclusion that it is only by means of the interposed air or other non-conducting medium that electrisation by influence is possible; that there is no electric action at a distance greater than the interval between two adjacent molecules of the medium; that there takes place in this medium a true polarisation of the particles, or a separation of their opposite electricities, whereby they become arranged into an alternate series or succession of positive and negative points or poles; and that it is by means of this polarisation of the particles that the force is transferred to a distance. So long as the particles of the medium retain this state of polarisation, insulation continues; but if the forces communicate or discharge one into the other, an equalisation or combination of the opposite electricities takes place throughout the whole series of particles. Faraday assumes that all the particles of matter are more or less conductors; that in their quiescent state they are not polarised, but become so by the influence of contiguous charged particles, in which case they assume a forced condition, and tend to return by a powerful tension to their original normal condition. Such particles being regarded as more or less conductors, they communicate their charge either bodily or by polarity, and contiguous particles impart their forces more or less readily to each other: when less readily, the polarised state becomes more exalted, and insulation is the consequence; when more readily, conduction results. Induction may therefore be defined as the action of a charged body upon insulating matter, the particles of which communicate the electrical forces to each other in an extremely minute degree, whereby they become polarised and propagate an equal amount of the opposite force to a distance. According to this theory, therefore, a charge is not retained on an insulated conductor by the pressure of the air, as was formerly supposed, but in virtue of the inductive action of surrounding surfaces through the polarisation of the interposed medium. It is a question of action and re-action: the insulated ball charged + produces an opposing but equal amount of — electricity, just as when we pull against a fixed point, that point offers an equal amount of resistance in the contrary direction.

The property possessed by the particles of matter to transmit the electric influence is termed *inductive force*, or *specific inductive capacity;* and this is found to be different in different insulating media. In order to compare them, the apparatus here represented in section was contrived. It consists of two metallic concentric spheres (A B), the space between the two (i) being destined for the reception of the substance whose inductive capacity was to be measured. The inner sphere is suspended by means of a metal rod, terminating at the top in a brass knob (C), and the rod is coated with a thick mass of shell-lac (s) to insulate it and separate it from the outer sphere. This is formed in two halves, like Madgeburg hemispheres [AIR], while a stop-cock (t) and a tube allow the air of the large sphere to be exhausted, and different kinds of gas to be let up into the interval: when solid media were introduced they were cut to the required shape. Two sets of apparatus were made, identically alike, for the sake of comparison. The apparatus was in fact a kind of Leyden jar, in which the two conducting coatings could be separated at pleasure by means of any required non-conducting medium. Now we know, in the case of a charged Leyden jar, that if it be made to communicate by its knob with the knob of an uncharged jar of precisely the same size, the latter will take from the former exactly one-half of the charge. Moreover, if we touch the knob of a charged jar with a small insulated conductor, such



as a gilt ball of light wood suspended by silk, or with a disk of gilt paper attached to a stick of resin and called a *proof plane*, it will take away from the charged jar a quantity of electricity of the same tension as that of the charge, and by this means the tension can be measured by a delicate electrometer. Now, in Faraday's first experiment, the interval *i* in both cases contained air, and the outer sphere was uninsulated. The small knob C being electrified, the inner sphere became charged, and the tension of the free electricity on its surface was measured by touching C with a proof plane and then trying it with a torsion electrometer. In this way a torsion of 250° was obtained, representing the tension on the sphere B. On bringing the ball C into contact with the corresponding ball of the second uncharged apparatus, the tension on the inner sphere of each apparatus became 125; or, in other words, the electricity had become equally distributed in the two instruments, as was to be expected, seeing that they were identical in make, and both contained air in the interval *i*. On filling up the lower half of this interval with a non-conducting body, such as a thick hemispherical cup of shell-lac, charging the other apparatus in which the interval, *i*, contained air as before, and measuring the tension on B, the number 290 was obtained. On dividing the charge between the two instruments there was no longer an equal division of the charge as before, such as $\frac{290}{2} = 145$, but the apparatus in which the interval contained air, gave a tension of 114 only, and the other apparatus with the shell-lac a tension of 113. Taking these numbers as equal, they differ considerably from 145, or half the charge, had both instruments contained air, and it appeared that whilst in the division the induction through the air had lost 176° of force, that through the shell-lac had only gained 113°. If this difference be assumed to depend entirely on the greater facility possessed by shell-lac, of allowing or causing inductive action through its substance than that possessed by air, then this capacity for electric induction would be inversely as the respective loss and gain indicated above, and assuming the capacity of the air apparatus as 1, that of the shell-lac apparatus would be $\frac{176}{113}$, or 1·55. Corresponding effects, in the reverse order, were obtained when induction through shell-lac was converted into induction through air, the force or tension of the whole being increased. As one-half of the interval contained air, this number would be too low to represent the specific inductive capacity of shell-lac. Other substances were tried in a similar manner, and they gave different values. One remarkable result was, that gases have the same inductive capacity, and that this is not modified either by their temperature, or by their pressure or their hygrometric state. Expressing, therefore, the inductive capacity of air by 1, the following numbers (obtained by Snow Harris by a totally different mode of experiment) represent the different substances named:—resin, 1·77; pitch, 1·80; yellow wax, 1·86; glass, 1·90; sulphur, 1·93; shell-lac, 1·95. Faraday has proposed to call these isolating bodies *dielectrics*, in contradistinction to conductors, which have no inductive power, that is, induction is not possible through conductors in communication with the ground.

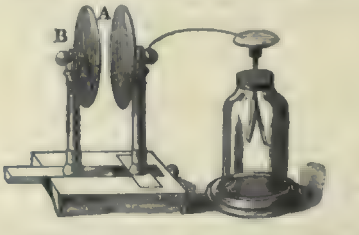
It has been urged as an objection to Faraday's theory that induction takes place in vacuo; but unless it can be shown that the most perfect vacuum which can be produced contains absolutely no material particles, the objection falls to the ground. Indeed it is a consequence of Faraday's theory that the fewer the particles of the dielectric the stronger is the charge or ultimate result. Nor does there appear to be any limit to the distance of the action. We have seen Faraday trace it from an electrified insulated ball placed in the middle of the theatre of the Royal Institution to the walls of the room.



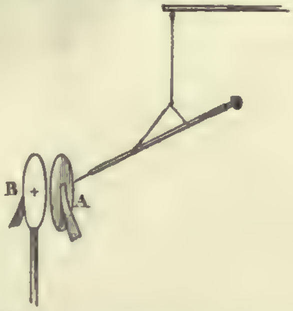
Seeing then that inductive action takes place through the particles of intervening matter, Faraday supposed that such influence was exerted, not in the direction of straight lines only as had been previously assumed, but also in curved lines. To test this opinion a cylinder of shell-lac, about an inch in diameter and seven inches long, was fixed in a wooden support; it had a concavity at the upper extremity for supporting a brass ball. The upper half of the cylinder was excited negatively, the brass ball was placed on the top, and the arrangement examined by means of the carrier ball and the torsion electrometer. When the carrier was made to touch the ball the two were uninsulated by touching them with the hand, then insulated as before, separated, and the charge of the carrier examined. In this way the force was found to vary in different positions. When the carrier was placed at *d* the effect produced was 512°, at *c* 270°, at *b* 149°; when not touching the brass ball at all, as at *a* and *e*, it was electrified also +, as in the other cases, and at *a* gave the highest result, or over 1000°. The charges obtained at *a*, *c* and *d* might arise from an inductive action in straight lines, but that at *b* was clearly in a curved line, since the carrier ball could not, from the size of the brass ball, be connected by a straight line with any part of the excited shell-lac, and the experiment is rendered still more decisive by placing the ball at a distance, and obtaining a discharge of positive electricity after uninsulating and then insulating it. If, instead of the ball, a brass plate be placed on the shell-lac, uninsulated, the carrier ball will show signs of electricity at various distances at the side and above the plate.

In good conductors the polarisation of the particles must, according to this theory, take place, but the discharge from particle to particle occurs so instantaneously, that they can only exhibit the polarised state as a whole, as in the case of an insulated sphere. Now it is evident that this result is brought about whether the body be solid or hollow, since the charge will be found only on the surface of conductors, for it is there only that the surrounding air or other resisting dielectric medium exists, and on this medium does the power of maintaining induction and consequently charge on the part of the insulated electrical body depend. The early electricians were not a little puzzled at finding no traces of electricity within a hollow insulated electrified conductor. Thus Priestley ('History of Electricity,' p. 688), says, "I electrified a tin quart vessel standing upon a stool of baked wood, and observed that a pair of pith balls insulated by being fastened to the end of a stick of glass, and hanging entirely within the cup, so that no part of the threads were above the mouth of it, remained just where they were placed without being in the least affected by the electricity." Many of Faraday's experiments beautifully illustrate the fact of the accumulation of the charge on the outside. For example, if an ice-pail be insulated and a brass ball also insulated be electrified and introduced into the vessel so as to touch it, and then be withdrawn, it will be found to have given up the whole of its charge to the pail. If now we introduce the proof plane, or the carrier ball into the vessel, no electricity will be carried away, but on touching the outside a full charge will be obtained. There can evidently be no charge within the vessel because there is no object towards which induction can take place. If, however, an uninsulated brass ball be held within the pail but without touching it, the particles of air will immediately become polarised, since the brass ball can assume an electrical condition opposite to that of the pail: the proof plane can then take away a charge from the interior as well as from the exterior of the vessel. If the pail be + the ball will be —, for its + electricity will pass to the ground along the conducting wire.

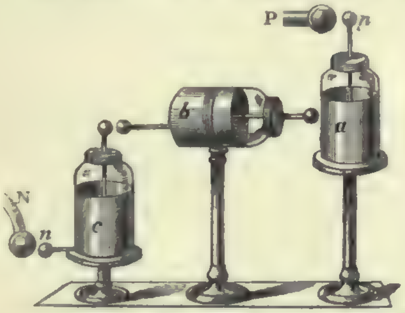
According to the new theory, the action of the condenser is thus explained:—If an insulated metal ball be charged and placed in the centre of a hollow sphere, induction will diminish in every direction as the square of the distance. If an uninsulated conducting surface be introduced, the induction will be diverted from distant objects, and the more so the nearer the conducting surface is brought to the charged ball. The surface will be electrified in an opposite state to that of the ball, and the fewer the intervening particles of the dielectric air, the stronger will be the polarity in them, and the more completely will induction be drawn off from distant objects. The tension of the interposed air may become so great that it ceases to insulate, and a discharge takes place between the two surfaces, manifested by a spark: for example, let a metal disk A insulated on a glass pillar, be connected by a wire with a gold-leaf electroscope, and a small charge of + electricity be given to A, so as to cause the leaves to diverge; if now a second metal disc B, uninsulated, be made to approach A, the gold-leaves will gradually collapse, but will open out again if B be withdrawn. This will take place a number of times, an effect which could not be explained by the old theory of a charge being retained by the pressure of the air. Now the action of the charged disc A is to decompose the electricity of B, to retain upon it an equivalent portion of — electricity, while the + electricity of B passes off to the earth. In consequence of this latter action the disc A may receive a considerable charge by repeated contact with a body very feebly charged, the excitation being renewed after every contact with A: during this time the plate B must be very near to A, and if B be suddenly withdrawn, the gold leaves will diverge, because the whole induction is now directed upon surrounding objects, instead of being limited by B.



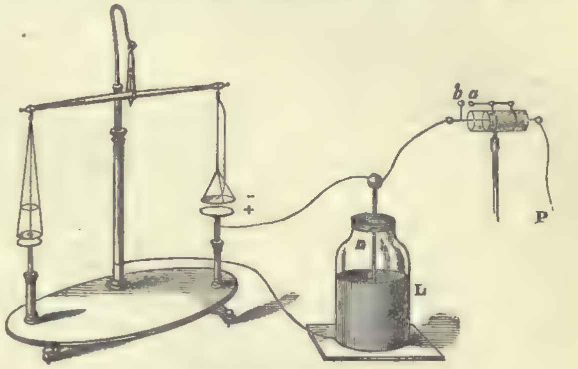
The opening out of the gold leaves in the above experiment by what is called electrical repulsion, is due to induction, for no electricity can be detected on the inner surfaces of the leaves, but only on the outer surfaces, as may be proved by substituting slips of gilt paper for the gold leaf, and when diverging under a charge, bringing a proof-plane into contact with them, and testing it by means of a torsion electrometer. The leaves diverge because induction takes place from their outer surfaces towards surrounding objects, which attract the leaves and cause them to separate from each other. If, however, an uninsulated body be placed between the leaves, induction takes place from the inner surfaces towards it, and they collapse. Every case of attraction is preceded by induction, for the opposed surfaces become oppositely electrified by polar action, and then attraction is possible. This may be shown by one of Harris's beautiful experiments, in which a disc of gilt card, A, three inches in diameter, is balanced at the end of a light rod of shell-lac and suspended by a thread. At the back of the disc is attached a slip of gold-leaf, and a similar insulated disc, also with a slip of gold-leaf at its back, is charged, say +, and brought up to the disc A, when it will be seen that the gold-leaf on A will open out, and then, and not till then, will the disc A be attracted to B.



The Leyden jar is an example of a solid dielectric between two conducting surfaces. A plate of glass partially coated with tin-foil would serve the purpose, only it is not so convenient a form as a jar. The glass should be thin, and the coating of tin-foil, both within and without, should extend to within two or three inches of the neck, the upper part of the jar being left uncovered, in order to insulate the two coatings. Through a wooden cover passes a wire, surmounted by a brass knob, and terminating in a brass chain for conveying the charge to the inner coating. On connecting the knob of the jar with the prime conductor of an electrical machine in action, bright sparks will pass from the conductor to the knob; the electricity passes down the wire, and by means of the inner metallic coating distributes itself over the interior of the glass, the particles of which become polarised, and thus decompose the electricity of the outside of the jar, leaving it in an opposite state. The electricity of the same name passes from the outer coating to the earth, so that it is necessary for the outer coating to be uninsulated. If the jar be insulated, as at *a*, only a feeble charge can be introduced into it, but if a conductor be held near the outer coating of the insulated jar, a spark will pass from the outer coating for every spark that strikes upon the knob, *p*, of the jar. In this way a number of jars, *b*, *c*, &c., may be charged by connecting the knob of one with the outer coating of the jar nearest to the prime conductor, P, of the machine, and the knob of the third jar *c*, with the coating of the second, *b*. In this way each jar may receive a powerful charge, although all be insulated except the last in the series, the outer coating of which must communicate with the earth, or a conductor, N, in communication therewith. It will be evident, however, that a charged jar does not contain a larger quantity of either electricity than it does in its neutral condition; only there is a different distribution of the force: in the uncharged jar the compound electricity is equally distributed within and without the glass; while in the charged jar, the electricity of one kind is accumulated on the interior, and that of the other kind on the exterior of the glass. That the charge is on the glass, and not on the coatings, may be proved by making the coatings moveable, when the jar can be charged, and the glass be separated from its coatings, and restored to them again without disturbing the charge. That the intervening glass or dielectric is molecularly polarised is proved by a good experiment by Matteucci: a number of thin plates of mica were placed one upon the other in a pack, and metallic plates being applied to the other pieces, the whole was charged like a Leyden jar. On separating the plates by means of insulating handles, each was found to be electrified, one side being positive and the other negative.



Advantage was taken of the properties of the Leyden jar by Harris, to construct what he calls the *unit jar*, for measuring out definite quantities of electricity. The unit jar is a small Leyden phial insulated on a rod of glass, with a wire attached to the outer coating, terminating in a knob, *a*, placed at a small distance from a similar knob, *b*, proceeding from the wire which passes into the interior. The bottom of the jar is also furnished with a knob, which may be connected by means of a wire with the prime conductor of the electrical machine, while the foremost knob of the unit jar may be similarly connected with the knob of a Leyden jar, the charge of which is to be measured. On turning the electrical machine, the outer surface of the unit jar becomes positively electrified, and an equal amount of positive electricity passes from the interior of the unit jar into the Leyden jar. As soon as the unit jar is fully charged, a spark passes between the balls, *a*, *b*, and equilibrium is for a moment restored; but as the machine is kept in action, the outer surface of the unit jar becomes again charged, an equivalent quantity of positive electricity passes into the Leyden jar, and the unit jar discharges itself as before. In this way by counting the number of sparks which pass between the knobs, *a* and *b*, a numerical value can be given to the charge of the Leyden jar. The distance between the balls, *a* and *b*, can be adjusted at pleasure; but supposing that distance to remain equal, successive charges in the Leyden jar will also be equal, provided the same number of sparks passing between *a* and *b* be counted for every charge.



By means of an apparatus of this kind and a modification of the common balance, Harris was enabled to measure the force of attraction between two charged surfaces. For one of the pans of the balance, a disc of gilt wood was substituted, beneath which was placed a similar disc insulated. Attached to the metal support of the balance beam was a wire connected with the outer coating of a Leyden jar, and the suspended disc was connected by conducting materials with the balance and the support, while the lower insulated disc was connected by a wire with the inner coating of the Leyden jar. The scale pan on the left contained grain weights, and the support underneath was to prevent the too great oscillations of the balance. On measuring off into the Leyden jar, by means of the unit jar, a quantity of electricity sufficient to produce between the discs an attractive force that would raise 4 grains in the opposite scale pan, it was found that a double charge of electricity would raise 4 times the amount, or 16 grains, while a triple charge would raise 9 times the amount or 36 grains, so that the area of charged surface remaining constant the attractive force increases as the square of the quantity. If a single charge consisting of ten sparks or units be divided between two Leyden jars presenting equal amounts of covered surface, the attractive force will be diminished to one-fourth, and with three jars to one-ninth, as compared with a single jar, so that a charge which in one jar would raise 18 grains would if diffused over two jars raise only 4½ grains, and if diffused over three jars, it would raise only 2 grains. Hence, the quantity of charge remaining the same, the attractive force is inversely as the squares of the charged surfaces of the jars.

When the electric equilibrium has been disturbed there are three modes in which it may be restored, namely, by *conduction*, by *disruption*, and by *convection*. When, for example, a charged jar is discharged by means of a discharging rod, the electricity is conducted quietly through the wire of the discharger so long as contact is maintained, but in traversing the air between the knob of the jar and that of the rod, a brilliant spark passes, accompanied by a crackling noise. After the jar has been discharged, a second smaller spark, known as the *residual charge*, may be obtained from it. Faraday considers this to arise from the circumstance that all bodies, including even resin and glass, have a certain amount of conducting power, by virtue of which a portion of the charge penetrates the substance of the dielectric, the two surfaces being in opposite states. As soon as the principal discharge has been made, and the force which caused this penetration removed, the electricity returns to the surface, re-charges the jar to a small extent, and thus accounts for the residual charge. As no substance insulates perfectly, so no substance conducts perfectly, since there is experimental proof that the resistance to discharge offered by a long thin wire may be greater than that offered by a stratum of air, so that the discharge will take place through the insulating air, rather than along the conducting wire. Indeed the resistance offered by conductors may be considered as insulation: increase the resistance, and the conducting power is diminished and the insulating power proportionally raised; but in general the resistance to conduction is manifested by the evolution of heat, the measure of which is inversely as the conducting power. Harris contrived a kind of air thermometer with a large bulb, across which could be placed wires of equal length and thickness, and he found that on discharging equal quantities of electricity through these wires in succession, he was enabled to assign numerical values to them, the smallest numbers being given to the best conductors, or those which emitted the least heat. Thus copper and silver were each represented by 6, gold by 9, zinc 18, platinum 30, iron 30, tin 36, lead 72. By alloying the metals with each other the conducting power was in some cases greatly reduced: thus, an alloy of 3 parts gold and 1 part copper, gave the conducting power of 25, while gold 1 and copper 3, gave only 15. Gold 3 and silver 1 = 25, tin 1 and lead 1 = 54, tin 1 and copper 3 = 11, and brass = 18. When different quantities of electricity were transmitted through the same wire, it was found that the increase in temperature was as the square of the quantity; so that if the thermometer with a given charge rose 10°, 4 times that charge were required to raise it twice that amount or 20°. Thin wires of silver, steel, platinum, copper, &c., can be readily fused and dispersed by sending a strong charge through them. The amount of such charge as measured by the unit jar is equally powerful, whether diffused over a large or a small surface. The intensity of the charge, as expressed by the quantity of electricity passing through a given space in a given time, is the same in the wire, although the intensity of the charge on equal surfaces of the jar may vary. It must be remembered that although in the charge we have chiefly to deal with surfaces, yet in the discharge, all the particles, (that is, the whole thickness of the conducting wire,) are concerned in the result. In the discharge by disruption, the particles of the di-electric gradually become more and more highly polarised or excited, the tension on one or more particles becomes so great as to exceed the limits of resistance, the opposite induced forces cease to balance each other, and the discharge passes along the line of least resistance, accompanied by light, heat, and noise; while portions of the solid conductors become detached and give characteristic colours to the spark. By this transference of metallic particles from one conductor to another, particles of silver may be precipitated on copper, and even made to penetrate its substance; and there are cases in which gold has been made to penetrate a plate of silver, and appear on the opposite side where the sparks passed. For some grand examples, however, of disruptive discharge we must refer to LIGHTNING.

We have seen that in air of whatever density (unless so rare as to conduct), the same amount of charge produces the same extent of conduction, other things being equal. The distance through which the discharge of equal quantities of electricity, or what is called the *striking distance*, takes places, varies inversely as the pressure. A double pressure doubles the number of aerial particles in the same space, and double the amount of insulating matter is required to be polarised; for example, if in air, at common pressure the striking distance be two inches, at double that pressure it would be one inch; halve the pressure and it would be 4 inches, at one-fourth the pressure 8 inches, and so on until *in vacuo* the striking distance would be unlimited. When the density of the air remains constant, the striking distance varies as the intensity of the charge. Thus, if the striking distance be with a certain charge 1 inch, at double that charge it will be 2 inches, at treble that charge 3 inches. But with equal charges the striking distance varies in different gases, irrespective of their relative density, so that each gas has a specific insulating power; thus hydrochloric acid has twice the insulating power of atmospheric air, and three times that of hydrogen of equal elasticity. When the discharge takes places between a good conductor presenting a small surface, and a bad one of larger surface, there is a rapid but intermitting succession of discharges to the particles of air around; and the sparks thus diluted form a *brush*, which has a quivering kind of motion, and is attended by a subdued roaring noise: its root is brighter than the rays. The phenomena of the brush vary in different gases, the most beautiful effects being produced in nitrogen. The largest brush is produced from a surface charged with vitreous electricity: when a point is held to a surface charged resinously, a *star* or point of light is produced instead of a brush. When the charge is feeble, discharge is sometimes effected by a quiet *glow* instead of the noisy brush, and *convection* then takes place, that is, a current of air conveys the charge to a distance, which current has sufficient force to give motion to electrical toys arranged for that purpose.

The duration of a flash of lightning, or of the spark discharge of a Leyden jar is so instantaneous, that the most rapid motions which we can give to machinery appear to be rest as compared with it. Thus, if we print the words AT REST in large letters on a disk of cardboard, and cause this to spin rapidly round upon an axis through its centre, the words will of course disappear; but if we allow the flash of a Leyden jar to illuminate the disk, the words may be read with perfect ease, since the light has come and gone before the disk had time to move through any appreciable space. In this way Wheatstone has shown that the light of the electric discharge lasts less than the millionth of a second. Suppose a small wheel of dull metal to contain 100 bright equidistant rays, and to revolve 10 times per second, or once in the $\frac{1}{10}$th of a second. The appearance of these radii, as seen by the reflected light of an electric spark, will differ according to its duration. If the time be infinitely short, the reflexion during $\frac{1}{10}$th of a second will give the appearance of 100 fixed luminous rays. If it last $\frac{1}{1000}$th of a second, the whole circle will be luminous, since the impression of each ray upon the eye will remain until that of the succeeding ray is produced. For a duration of $\frac{1}{2}$, $\frac{1}{3}$rd, $\frac{1}{4}$th, $\frac{1}{5}$th, &c., of $\frac{1}{1000}$th of a second, corresponding illuminated segments will be seen, and $\frac{1}{2}$nd, $\frac{2}{3}$ds, $\frac{3}{4}$ths, or $\frac{4}{5}$ths of the circle will appear deprived of light, that is, there will be alternate bright and dark spaces corresponding to those quantities. By increasing the size of the wheel, the scale of these measures may be augmented, as may also its subdivision by increasing the velocity, or by multiplying the number of the spokes. By a modification of this apparatus, called the *Chronoscope*, Wheatstone was able to measure the velocity of the discharge of a Leyden jar through an insulated copper wire, and he estimated it 288,000 miles per second. ('Phil. Trans.,' 1834.) The copper wire was about half a mile in length, and was broken at three points, one within a few feet of the inner coating of a Leyden jar, a second in the middle of the wire, and a third near the outer coating of the jar, and the wire was so contorted that these three breaks were arranged side by side on an insulated disk or *spark board*, so that the three sparks could be seen simultaneously. When the jar was discharged through this half mile of wire the three sparks appeared to be simultaneous, but when seen by reflexion in a small steel mirror rapidly revolving on an axis parallel to its surface the sparks did not appear as points of light in the same horizontal line, but gave the appearance of three bright lines of equal length; the two outer lines were found to begin and end within the same horizontal space, but the middle one coming a little later than the others, the angular position of the mirror advanced somewhat before the middle spark made its appearance. Now, as the velocity of the mirror was known, and the amount of angular deviation of the central spark could be easily ascertained, the retardation of the discharge by the copper wire, or the velocity with which it moves through it, can be estimated. Professor Miller, who in his 'Elements of Chemistry,' part 1, gives a succinct but masterly sketch of modern electrical science, remarks that this experiment "affords a convincing proof of simultaneous action and reaction in the operations of electricity, and of its existence as a duplicate force: at the same moment that a positive influence leaves the inner coating, an equal amount of negative influence leaves the outer coating, and these two neutralise each other at the central point of the conductor, after the lapse of an extremely minute but still appreciable interval of time. It appears from this experiment that Franklin's theory, though in many cases a simple and convenient mode of explaining facts, is not the true representation of the phenomena. The theory of two fluids, or rather of two forces, acting in opposite directions, seems by this experiment to be demonstrated." It must be remarked, however, that the velocity of the electric discharge varies with the intensity of the charge and the nature of the conducting medium.

ELECTRICITY, ATMOSPHERIC. The similarity of lightning to the spark obtained by friction from an electrical apparatus was observed by the earliest experimenters in electricity; and in one of Franklin's letters, written apparently before the year 1750, the points of resemblance are distinctly stated. The first fruit of this discovery was the employment of thunder-rods for the protection of buildings and ships; and rods or wires projecting above the tops of edifices were soon extensively used by philosophers for the purpose of enabling them to ascertain the nature and intensity of the electricity in the atmosphere. Such means are not unattended by danger; and science has to record the death of Professor Richman, during a thunder-storm, while attending to the indications of the electrometer connected with an apparatus of that kind. [LIGHTNING.]

Franklin in America, M. de Romas in France, and Cavallo in England, each employed, for the purpose of bringing electricity from the atmosphere to the surface of the earth, a kite made of silk stretched on a frame, from the upper part of which projected a piece of pointed metal, and from which proceeded along the string a slender metallic wire. M. Buffon, M. Lemonnier, and others, planted vertically in the ground poles, from 30 to 40 feet in height, carrying at the top a pointed piece of tin or iron, from which descended a metallic wire. M. Mézèas in France, Mr. Ronayne in Ireland, and Mr. Crosse in England, employed long wires in horizontal positions, which were insulated by being stretched between two glass pillars, each on the top of a pole planted in the ground. The wire used by Mr. Crosse was 1800 feet long, and was above 100 feet from the ground. MM. Becquerel and Breschet examined the electric state of the air in the upper regions by means of a cord covered with tinsel about 90 yards long, one end of which was placed on the cap of a gold leaf electroscope, and the other was attached to a metal arrow which was shot into the air. The gold leaves were seen to diverge in proportion to the ascent of the arrow. (Becquerel, 'Traité de l'Electricité,' t. iv.)

The numerous experiments made by Cavallo serve to prove that the electric fluid always exists in the atmosphere, but in very different quantities at different times, and that it is more abundant in the higher regions than near the earth. The same philosopher found, also, that it is more intense in frosty than in warm weather, and that fogs are accompanied by a great quantity of electricity, except when they become rain; in this case little electricity is perceptible, the rain conducting to the earth the electricity of the air above. In high winds, also, the intensity of the atmospherical electricity is generally diminished, probably because the strata of air containing different quantities of the fluid are brought successively to the ground, and thus there is produced a nearly uniform distribution of the fluid between the earth and the atmosphere. It may be easily conceived that, in stormy weather, the variations of the atmospherical electricity will be very irregular; for currents of air in the upper regions, driving the strata of clouds in different directions, the electrical actions between the clouds and the atmosphere below must be extremely complex.

M. de Saussure has observed that, during summer and winter, by night as well as by day, when the atmosphere is free from clouds, the electricity of the air is positive; and Mr. Read ('Phil. Trans.,' 1794) has shown that out of 404 observations made in one year, the air was positively electrical in 241, negatively in 156, and that the electricity was insensible in 7 observations only. It seems probable, in fact, that the negative electricity which may be observed in a pure atmosphere is caused by the discharge of its positive electricity into the earth or a cloud, when one or the other of these is in a contrary state. Mr. Ronayne, however, states ('Phil. Trans.,' 1772) that in Ireland the electricity of the atmosphere is positive in winter when the air is clear: he observes that it diminishes in frosty or foggy weather, and that he could detect no electricity in the air during the summer except when a fog came on; the electricity was then positive, but it was less intense than during the winter fogs. It was an observation of Saussure that electricity is strongest in the open air, and that it is weak in streets, in houses, and under trees. In close rooms and hospitals the electricity of the air has been always found to be negative; such also is the electricity of the atmosphere when it is vitiated by exhalations from lime, paint, and decaying vegetables. [OZONE.]

All observations concur in showing diurnal variations in the intensity of atmospherical electricity, but there is some uncertainty concerning the precise times at which the intensities are the greatest and the least. Cavallo observed that in dry weather the electricity was weakest at sunrise; that it attained the maximum of strength in the day-time, and continued in that state till sunset, when the intensity diminished. He conceived that this diminution was much more rapid as the air became more humid; and he observed that in winter, when a dry wind prevailed, if the sky were free from clouds, the electricity became very strong after sunset. M. de Saussure observed at Geneva (1785) that, during winter, the intensity of atmospherical electricity attained its first maximum at 9 A.M.; that it diminished till 6 P.M., when it was in a minimum state; it afterwards increased, and attained its second maximum at 8 P.M.; after which it continued to diminish till it was again a minimum at 6 on the following morning. The same philosopher found that in summer the diurnal variations were less perceptible: on a dry warm day he found the electricity increase from sunrise, when it was almost insensible, till 3 or 4 P.M., when it became a maximum; it appeared then to diminish till the dew fell, when it became stronger, but it was scarcely sensible during the night. Lastly, the experiments of Mr. Read exhibit two maxima and two minima in twenty-four hours. The atmospherical electricity seemed strongest at two or three hours after sunrise, and again about sunset; it was weakest at noon and at 4 P.M.

The experiments of Mr. Crosse show also that, in the ordinary state of the atmosphere, the electricity is positive, and that it increases in proportion to the elevation above the earth's surface; the same philosopher observes that it is most intense at sunrise and sunset, and weakest at noon and during the night. He finds that the approach of a thundercloud produces a change in the electricity of the atmosphere, rendering it positive if it were before negative; and the contrary: whatever be the nature of the change which takes place, the intensity of the electricity increases to a certain degree; it then diminishes and disappears, and is succeeded by an opposite electricity: this gradually increases till it becomes of higher intensity than the former kind, and then it decreases till it vanishes: it is again succeeded by the first kind. These changes are often found to take place several times successively. Fogs, rain, snow, &c., also change the electricity from positive to negative, again from negative to positive, and so on; the change taking place every three or four minutes. A cold rain, in large drops, is frequently accompanied by intense electricity; and during a driving fog or rain the electricity is occasionally as strong as during a thunder-storm. A warm small rain is weakly electrified; and a weak positive electricity generally prevails during cloudy weather. Mr. Crosse finds also that the electricity of the air is very weak during the north-east winds which in winter and spring times produce extreme cold and dryness.

The intensity of atmospherical electricity has been observed to undergo annual changes; it increases from July to November inclusive; so that the greatest intensity occurs in winter, and the least in summer.

Any of the different kinds of electrometer may be employed to determine the nature and intensity of atmospherical electricity. [ELECTROMETER.] Professor Loomis states (Poggendorff's Annalen, Band 100), that the telegraphic wires are very sensitive to an approaching thunder-storm, and often become highly charged even when a storm is so distant that neither thunder nor lightning can be appreciated; but if the thunder-cloud be near, the wires may become so highly charged as to injure the magnetic apparatus and expose the clerks to considerable danger. Such effects, however, are not peculiar to America.

Later observations have confirmed the conclusion that the usual electrical condition of the air is positive. Out of 15,170 observations made at the Kew Observatory, during a period of 5 years, 14,515 are of positive electricity, and 655 of negative. During the years 1845, 1846, and 1847, out of 10,500 observations, 10,176 showed positive, and only 324 negative electricity; the latter being usually accompanied by heavy rain. The tension of atmospheric electricity was found to be at its minimum at 2 a.m., from which hour there was a gradual increase until 6 a.m.; after which the tension increased more rapidly, its value at 8 a.m. being nearly double that at 6 a.m.: the increase then became more gradual until 10 a.m., the period of the first or morning maximum: from this hour it gradually declined until 4 p.m., when it was only a little higher than at 8 a.m.; it then increased rapidly until 8 p.m., and after a slight rise at 10 p.m., the time of the principal or evening maximum, the tension was found no longer to increase. The evening maximum was much higher than that of the morning. Between 10 p.m. and midnight the tension decreased nearly to that of the diurnal minimum. With regard to the annual period the lowest tensions were found to be in June and August, the tension during July being slightly superior to that of those two months. There is a slight elevation in September, which increases in October, and more rapidly from November to January. The maximum is in February. In March a rapid diminution sets in, and proceeds to the minimum in June.

During four years' observations made at Brussels by M. Quetelet, the maximum was found to be in January, and the minimum in June. Expressed numerically the maximum had the value of 605°, and the minimum 47°; so that the electricity in January is thirteen times more energetic than in June. The difference was found to be much more sensible during serene than cloudy weather, and, setting out from June, the electricity of the air in serene weather was found to exceed the electricity observed during a clouded sky, in proportion as January was approached, in which month the ratio was more than 4 to 1. The powerful electric intensity of the air during a serene sky in winter must be considered as a remarkable fact. A high electric intensity was always observed during fog and snow.

Atmospheric electricity seems to depend for its supply chiefly on evaporation. It can be proved by experiment that the evaporation of water from heated bodies disturbs the electrical equilibrium, the + electricity being carried off by the vapour, while the − electricity is left behind in the vessel, or is carried off by its support. In order to produce this result, however, some chemical change seems to be necessary, since the evaporation of pure water fails to produce electrical disturbance. When water is evaporated from alkaline solutions the vapour carries off − and leaves + electricity behind; but the reverse of this takes place when water is evaporated from an acid or from neutral saline solutions, including sea-salt. During the processes of vegetation, in which water is largely separated from the other constituents of plants, there is also electrical disturbance. Volcanic eruptions and conflagrations are also accompanied by strong electrical excitement. The friction of wind, dust, &c., is also a source of atmospheric electricity. Dr. Livingstone ('Missionary Travels, &c., in South Africa,' 1857) states that in the Kalahari Desert, during the dry season, a hot wind occasionally blows, and it is "in such an electric state that a bunch of ostrich feathers held a few seconds against it, becomes as highly charged as if attached to a powerful electrical machine, and clasps the advancing hand with a sharp crackling sound." Even the motion of a native in his kaross is sufficient to produce therein a stream of small sparks.

There are many difficulties in accounting for the presence of free electricity in the air. Perhaps the best theory is that started by Eales ('Phil. Trans.' 1757-8), and extended by Sir John Herschel ('Encyc. Brit.,' 8th ed., Art. Meteorology). We will state sufficient to indicate the nature of the theory. When water evaporates it is supposed to pass off in the form of little vesicles of moisture, each vesicle charged with electricity of too low a tension to discharge itself into neighbouring vesicles, or to escape by conduction through a moist atmosphere. If, however, a tall pointed conductor, a flame, or a column of smoke, be introduced, the air may give off a portion of electricity by contact discharge. But if we suppose a number of the particles of vapour thus electrified to be condensed by cold into a drop of water, the whole of the electricity would be collected on the surface of such drop with a corresponding increase in tension. Suppose one such drop to be 1000 times the size of one of its constituent particles, the diameter will be increased 10 times and the surface 100 times, while the electricity being the sum of the 1000 globules will be increased 1000 times on the surface of the drop with a tenfold density or tension. The comparatively high electric state of fog, and of snow, is thus explained. Every globule of moisture of which it consists has a coating of electricity, which it will part with to the surface of any conductor, and the denser the fog, and the larger its globules, the greater is the quantity of electricity set free. This theory also explains the electricity of the air as occasioned by the deposit of dew, and also the daily variation in tension; for the air losing a great deal of vapour by a deposit of dew, by night the electricity is at its minimum. It increases as fresh vapour arises under the influence of the ascending sun; decreases as the growing warmth of the air enables it to hold a still larger amount of vapour uncondensed, and as the vapour itself rises rapidly to form cloud; increases again towards the evening, when dew begins to form at sunset and vapour to settle into globules, and once more decreases as the number of these electrified globules diminishes by deposition and diffusion. A large portion of the electricity near the surface is returned to the earth by slow conduction, and the more so in proportion as the air is moist. The great and sudden increase of electrical tension, sufficient to produce a flash of lightning, and a torrent of rain, will be noticed under LIGHTNING; RAIN.

The aurora borealis, and some other meteoric appearances, have been ascribed to the electricity of the atmosphere. [POLAR LIGHTS.]

ELECTRICITY, ANIMAL. [ELECTRICITY OF ORGANIC BEINGS, NAT. HIST. DIV.]

ELECTRICITY, *Medical application of.* A supposed analogy between electricity and the nervous power has led to the employment of this agent, particularly in diseases connected with defective nervous energy, and also in cases of defective secretion, perhaps originating in a similar cause. The influence of electricity on the human system differs much according to the manner in which it is applied, the length of time during which it is continued, and the degree of intensity. It also differs in its action according as it is abstracted from, or communicated to, the individual. When applied in a moderate degree of intensity, it occasions an increase of nervous action, of sensibility and irritability, more vigorous circulation of the blood, augmented warmth, and secretion, especially cutaneous transpiration: even the exhalation of plants is much increased by electricity. When the electric principle is more intense, all these actions are heightened, often to a painful degree; while such a degree of concentration as occurs during certain atmospheric changes can occasion instant death. Death occasioned by this means is always followed by rapid decomposition of the body. The diseased states in which electricity has been found most useful are—in asphyxia, from any cause (except organic disease of the heart), but particularly from exposure to irrespirable gases; in certain asthmatic diseases; and dyspepsia, dependent on irregular or defective supply of nervous energy to the lungs and stomach. It is, however, much inferior to galvanism as a remedial agent in these diseases. (Wilson Philip 'On the Vital Functions.') In local paralytic affections, when of a chronic character, electricity, duly persevered with, has been found very useful: in a case of dysphagia, from paralysis of the œsophagus, the patient could only swallow when placed on a seat resting on non-conductors and electrified. In deafness and loss of sight, when directed by a competent judge, it has restored the functions of seeing and hearing. Lastly, in defective secretion, especially amenorrhœa, it has proved of service. Recently, M. Becquerel and others have employed electricity, with complete success in six cases, where the milk has been suppressed, as an exciter of the mammary secretion.

ELECTRO-CHEMISTRY. Electricity, like heat and light, both affects and is affected by chemical change: and just as heat more often appears as a cause or consequence of chemical change than does light,—so galvanic, or low-tension (voltaic) electricity is more prominently concerned as cause or effect in chemical change, than is the so-called frictional or high-tension electricity. Hence, in electro-chemistry, the relation of chemical change to galvanic electricity has almost exclusively to be considered.

The order will be adopted of considering (1) the chemical changes effected by a galvanic current; (2) the galvanic current produced by chemical changes.

If the two poles of a battery be brought into contact with two points of a homogeneous substance, the substance may either conduct the current without suffering chemical change, it may refuse to conduct the current at all, or finally it may conduct the current and suffer chemical change.

No instance is known in which a true chemical compound conducts a current without suffering chemical alteration; but substances which are simple, as far as evidence goes, may refuse to conduct a current. Moreover no chemical compound substance conducts unless in a state of liquefaction, such liquefaction being caused either by solution in media or by igneous fusion.

As a class, the metals are the best conductors of electricity. With regard to the resistance offered to a galvanic current by various conductors, some of which are unaltered, some decomposed by it, we may compare the numbers of the following table (Buff, Zamminer, and Kopp's 'Lehrbuch'), in which the resistance to the same galvanic current offered by the same lengths and thicknesses of some conducting substances is given, the resistance offered by silver being taken as unity:—

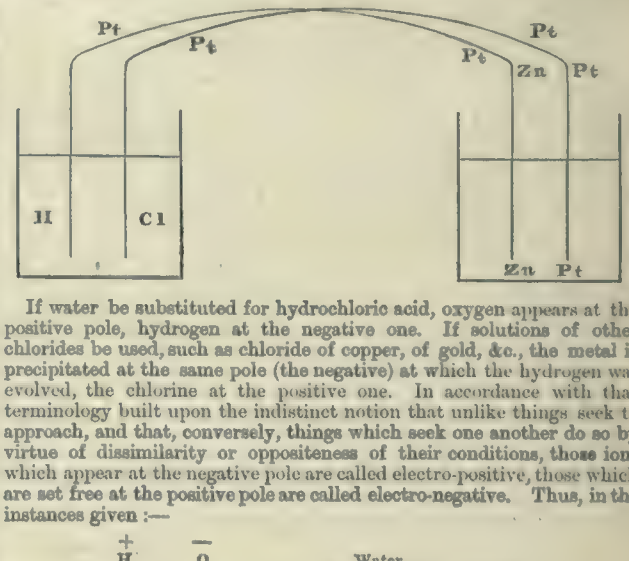
Silver	1·000
Copper (chemically pure)	1·043
Copper (commercial)	1·270
Brass (composition not stated)	5·372
Iron	8·427
Platinum	9·590
German silver (composition not stated) . .	12·400
Mercury	29·238
Sulphuric acid (sp. gr. 1·2 to 1·36) . . .	761732·000
Sulphate of zinc (33·58 *per cent.* of anhydrous salt in solution	11019012·000
Sulphate of copper (20·83 *per cent.* of anhydrous salt in solution)	14809320·000

From what has been said, it follows that the latter three of these substances are decomposed during the passage of the current through them. The presence of more than one element in brass and German silver is not in contradiction to the general rule laid down; for the metals present in these alloys are not in chemical union, and the alloy conducts the current in the same manner as would a bundle of wires consisting in part of one metal, in part of the other. The conducting power of the metallic conductors is diminished by an increase of temperature, that of the compound solutions is always increased.

In examining the nature of the changes wrought in compound conductors when submitted to, and therefore decomposed by, the electric current, it will be convenient to suppose, in the first place, that the poles by which the current is led through the substance are themselves chemically inactive, that is, of such a nature as not to be acted on by any of the products of decomposition. In practice, when this passivity is desired, the poles are usually made of platinum, and this will in the sequel be always tacitly assumed to be the case, unless the contrary be expressed.

The decomposition of a compound substance by galvanic electricity is called the *electrolysis* of that substance. The body so decomposed is called an *electrolyte*. The two poles between which the current passes through the electrolyte are the *electrodes*. The positive (+) electrode, or *anode*, is the one in metallic connexion with the inactive element of the battery (Platinum, Carbon). The negative (—) electrode, or *cathode*, is in connexion with the active or attacked element of the acting battery (Zinc). The products of electrolysis of the electrolyte are sometimes called *ions*. That *ion* which appears at the negative electrode or cathode is the *cation*; that at the positive electrode or anode is called the *anion*. (According to strict analogy, this latter nomenclature should be inverted.)

Thus, if the two platinum poles of a battery be inserted into a solution of chloride of hydrogen (hydrochloric acid), chlorine is liberated at the positive electrode or pole, and hydrogen at the negative one: in the manner of the skeleton diagram:—



If water be substituted for hydrochloric acid, oxygen appears at the positive pole, hydrogen at the negative one. If solutions of other chlorides be used, such as chloride of copper, of gold, &c., the metal is precipitated at the same pole (the negative) at which the hydrogen was evolved, the chlorine at the positive one. In accordance with that terminology built upon the indistinct notion that unlike things seek to approach, and that, conversely, things which seek one another do so by virtue of dissimilarity or oppositeness of their conditions, those ions which appear at the negative pole are called electro-positive, those which are set free at the positive pole are called electro-negative. Thus, in the instances given:—

+	—	
H	O	. . . Water.
H	Cl	. . . Chloride of hydrogen.
Cu	Cl	. . . Chloride of copper.
Au	Cl	. . . Chloride of gold.

the elements in the first column are electro-positive, those in the second electro-negative.

If now, instead of binary compounds of this kind we submit aqueous solutions of oxygen acids, or salts of such, to electrolysis, we find that in the first instance, that is, in the case of the free acids (or hydrogen salts) hydrogen is liberated at the negative pole and oxygen at the positive one. If a metallic salt of such an acid be electrolysed, the metal is deposited at the pole where hydrogen is liberated, while oxygen, as before, escapes at the positive pole. It is by laying weight upon the analogy of decomposition, in the cases of binary salts and oxygen ones, that the similarity of their constitution has been supported. For, if we imagine the electric current to enter the electrolyte by the positive pole (anode), and to withdraw all the negative atoms (chlorine) of the molecules of hydrochloric acid in contact with it; as the hydrogen so freed does not escape *in loco*, it is easy to imagine the atoms of hydrogen to decompose the molecules of hydrochloric acid in their neighbourhood, liberating hydrogen again, and that these decompose fresh molecules of hydrochloric acid, liberating hydrogen, and so on. So that, wherever the cathode may be, that is, wherever the negative pole is situated and such successive decomposition has to cease, in consequence of the current finding a metallic conductor (the cathode) by which it may leave the electrolyte, it is clear that there hydrogen will be evolved. As the results of the electrolysis of sulphuric acid and the sulphates are analogous with those of hydrochloric acid and the chlorides, namely the appearance of hydrogen or metal at the negative pole, and oxygen or chlorine at the positive one, it is not difficult to suppose the two to be similarly constituted; and that sulphates, nitrates, &c., are made up, like the chlorides, of two parts, one electro-positive the other electro-negative :—

+	—	+	—
H	Cl	H	SO_4
Cu	Cl	Cu	SO_4
		Cu	NO_6

This hypothesis of the constitution of oxygen salts is supported by the law of equivalent electrolysis, which we shall discuss directly. It requires, however, the assumption of hypothetical substances, SO_4, NO_6, &c., which are not separated as such, like chlorine, but must be decomposed, as soon as formed, into oxygen, which appears, and the anhydrous acid, SO_3, NO_5, &c., which finds water with which to combine. It is these hypothetical molecules, SO_4, NO_6, &c., which must be supposed to be successively liberated by the liberated atoms of hydrogen or metal from the molecules of the salt, in the same manner as is the case with the halogens in binary compounds. However, the necessity for this hypothesis cannot be considered as very hostile to the haloidal constitution of oxygen salts, for many instances are known where the actual ultimate products of electrolysis (or ions) appear, by the strongest possible analogies, to be products due to the chemical action between the initial ions and the unaltered electrolyte in contact with them. Thus, if instead of chloride of copper, chloride of sodium be submitted to electrolysis, chlorine as before is evolved at the positive pole, while at the negative not sodium but hydrogen is evolved. Now Cu Cl and Na Cl are certainly chemically similar. Further, if the anhydrous salt be employed in the fused state, sodium is actually liberated: finally, if sodium were set free in an aqueous solution at the negative pole, the products would be the same as they are actually found to be, for water would be decomposed, soda formed, and hydrogen evolved. Again, by altering the nature of the positive electrode, we may affect the nature of the ion appearing there. Thus, if the electrolyte be dilute sulphuric acid, and the positive electrode be of zinc amalgam, the oxygen which, had the positive electrode been platinum, would have been liberated there, combines with the zinc and dissolves as sulphate of zinc in the sulphuric acid. Or, further, even by altering the strength of the electrolyte (sulphuric acid), the products may be affected; for unless the acid be dilute, a part of the oxygen, instead of escaping as such, combines with the water to form HO_2, which dissolves in the electrolyte. It is, indeed, on the power we have of altering the nature of the ions, that the construction of constant batteries depends. In Daniell's for instance, the hydrogen, which would collect at the negative pole (which is of copper) and check the current by interposing a partial cushion of a non-conducting gas, is made, by placing a solution of sulphate of copper round this pole, to precipitate an equivalent (chemical and electrical) of metallic copper, itself being converted into water and combining as such with the sulphuric acid of the sulphate of copper; whereby the electrode continues to be coated with fresh portions of metallic copper. In Grove's and Bunsen's batteries, again, the hydrogen which would be liberated at the negative pole is there instantly oxidised to water by the nitric acid which surrounds it.

In organic compounds, where the electrolyte is often of a very complex nature, it is frequently difficult or impossible to recognise the primitive ion, and to distinguish it from the products of its action upon the electrolyte in contact with it.

It is in considering the products of electrolysis, or ions of an electrolyte, that the atomic theory receives prominent illustration; or, conversely, it is from the atomic hypothesis that the clearest light is thrown upon the process of electrolysis.

Suppose the current from a battery to pass by one electrode into a vessel of water: let the other pole be immersed in a vessel of chloride of copper, and let an arc of platinum be placed with one limb in each vessel. The current from the battery will enter the water by the positive electrode P_1, will traverse the water and escape by the negative electrode N_1; passing along the arc, it will enter the solution of copper by the positive electrode P_2, traverse it, and escape by the negative electrode N_2: thus regaining the battery after having traversed both vessels. Now from what has been said before, it is self evident that for every atom or equivalent of oxygen liberated at P_1 there must be an equivalent of hydrogen liberated at N_1, that is, if the whole of each ion set free escapes. Further, that for every atom or equivalent of chlorine liberated at P_2, there must be an atom or equivalent of copper deposited at N_2 (under the same restriction). In other words, the hydrogen and oxygen will be in the proportion of 1 to 8, and the copper and oxygen in that of 1 to 0·25. So much is in accordance with the purely chemical law. But it is further found that the quantity of hydrogen in the first vessel is to that of copper in the second as 1 to 32, and therefore to that of chlorine as 1 to 35·5, so that the quantities of all four ions are in the proportion of their equivalents. The same is true, however many electrolytes a current has to decompose in its course, and this constitutes the great law of *equivalent electrolysis*. It is easy to understand that the same law is essentially true when the primitive products of decomposition undergo further change in presence of the electrolytes. Thus, if a current traverses two neutral solutions, the one of sulphate of potash the other of phosphate of soda, each of which is divided into two portions by a porous diaphragm in such manner that the sulphuric and phosphoric acids, freed at the positive electrodes, shall not mix with the potash and soda at the respective negative poles; then, however long the current has passed through, not only will the liberated phosphoric acid exactly neutralise the liberated soda of the same cell, it will also neutralise the caustic potash of the other one; and the same is true *mutatis mutandis* of the sulphuric acid. For the metals potassium and sodium, initially separated, being equivalent, will by their oxidation give rise to equivalent quantities of potash and soda. The meaning then of the law of equivalent electrolysis is, that the power which a current possesses of effecting chemical change is exerted throughout its course in equal degrees wherever such chemical change is effected.

It follows that by ascertaining the whole amount of one ion liberated at any electrode of a current which passes through any number of electrolytes, we ascertain the quantity of every other ion liberated by the same current (or, of its equivalent derived by secondary change). A practical application of this is exemplified in the construction and use of the voltaic electrometer or voltameter. This instrument is, in fact, nothing more than a cell containing acidulated water, which is introduced into the current and decomposed by its means between two platinum electrodes. By a simple arrangement, the amount of hydrogen liberated at the negative electrode is collected and measured. Or the oxygen and hydrogen from the positive and negative poles are collected together. In the latter case, of course, for every 9 parts by weight of the mixed gases, every other ion freed in the circuit has been liberated in quantity proportional to its equivalent. The hydrogen liberated at the negative, and the oxygen liberated at the positive pole exhibit all the powerfully developed affinities of these elements in the nascent state. Thus many oxygenated or chlorinated organic bodies which refuse to part with their oxygen or chlorine under ordinary conditions, and which may refuse to conduct the current when pure, will give up their electro-negative elements to the hydrogen at the negative pole of a galvanic current when, by mixture with an acid and aqueous solution, they are made to conduct, and hydrogen is furnished. Under the same conditions many substances may be oxidised by the oxygen liberated at the positive pole. Thus by mixing chloroform with alcohol and dilute sulphuric acid, and submitting the mixture to electrolysis, the hydrogen at the negative pole replaces the chlorine of the chloroform, and hydride of methyl, or marsh gas is formed. Again, if a solution of caustic potash be submitted to the action of a current, the positive electrode of which is metallic iron,—the iron becomes peroxidised to ferric acid, and ferrate of iron is formed at this pole. So, a solution of cyanide of potassium gives when similarly treated, cyanate of potash at the positive pole. The same powerful affinity is exhibited by other electro-negative ions; thus, for instance, when chloride of ammonium in solution is electrolysed, chloride of nitrogen is formed at the positive pole. It will, however, be borne in mind, that a part of the oxidising action of electrolytic oxygen may be due to the formation of binoxide of hydrogen, as before mentioned, or perhaps, to that of a still higher oxide (ozone). That the electrode itself may undergo change by the action of the ion liberated upon it, has already been exemplified. An instructive instance is furnished by the electrolysis of fused chloride of silver, when the electrodes are of silver. In this case silver is deposited in crystals upon the negative electrode, while the chlorine at the positive one combines with the silver of which that electrode is formed. Thus the amount of chlorine in the electrolyte remains unchanged, but fresh portions of silver are continually being transferred through it, from the positive to the negative electrode.

If a current be led through a solution of various metallic salts, the metal precipitated at the negative pole is not an alloy of all the metals present. Some metals are precipitated in preference to others, and the whole quantity of one metal present is precipitated before the second commences to be thrown down. Thus, from a solution of copper and iron salts, the copper is precipitated before the iron, from a mixture of iron and zinc salts the iron is precipitated before the zinc; finally, from a mixture of copper, iron, and zinc, the copper is precipitated first, then the iron, and lastly the zinc. Zinc is thus said to be more electro-positive than iron, iron more electro-positive than copper, &c. Compared with regard to their electro-positive characters the metals are related to one another as follows :—

Potassium,
Sodium,
Manganese,
Zinc,
Cadmium,
Iron,
Nickel,
Cobalt,
Lead,
Tin,
Copper,
Silver,
Mercury,
Palladium,
Platinum,
Rhodium,
Iridium,
Gold.

The first being the most positive, the last the most negative.

It is by the use of compounds free from water, and rendered conductors by fusion, that the most easily oxidisable metals are reduced from combination by means of the electric current. Thus, fused caustic soda yields oxygen at the positive pole, and metallic sodium at the negative one. The chlorides of aluminium, magnesium, barium, calcium, etc., yield up their metal at the negative pole. In such electrolysis, special precautions must be taken to prevent the metal from becoming re-oxidised, for the details of reduction by such means, see Aluminium, Calcium, Magnesium, &c. It may be here mentioned, that for this purpose it is usual to employ mixed chlorides, the melting points of such mixtures being lower than those of the simple chlorides, and the purity of the reduced metal not being impaired by the presence of other metals in the electrolyte, because the more electro-positive is separated in preference to the less electro-positive.

An example of the importance of the light which may be thrown upon the constitution of a compound substance by the electrolytic separation of its parts into the most electro-positive and electro-negative of its constituents, is furnished by the behaviour of the salts of the fatty acids towards the electric current. If valerianate of potash, whose empirical formula is $KO\,C_{10}H_9O_3$, be electrolysed by means of platinum electrodes separated by a porous diaphragm, potassium (that is, potash and hydrogen), appear at the negative pole, while carbonic acid and butyl appear at the positive.

$$\underbrace{KOC_{10}H_9O_3}_{\text{Valerianate of potash.}} + nHO = H + KO + \underbrace{C_8H_9}_{\text{Butyl.}} + 2CO_2 + (n-1)\,HO$$

Whence the formula expressing the electro-chemical constitution of valerianic acid is derived.

$$H,\ C_8H_9,\ 2CO_2.$$

If a piece of zinc be immersed in a solution of dilute sulphuric acid, so that a part of it is above the liquid, an inactive metal, such as platinum (that is, one which is not attacked by the acid), which connects the part of the zinc attacked with the part above the liquid, is found to be traversed by an electric current. This is the type of the formation of all electrical currents by chemical change. And if we assume arbitrarily that the current passes only in one direction,—namely, from the part of the zinc attacked to the part unattacked,—then the direction of the current in this example gives us the direction of the current in all other cases where metals are attacked by acids. Hence when, in the same acid, two metals are placed, of which the one is attacked, the other unattacked, by the acid, a current passes through the liquid from the attacked to the unattacked metal, if metallic contact be established between them above the liquid. But if such metallic connector be broken, and the ends plunged into a liquid containing an electrolyte (*fig.* 1), then such an arrangement of active and passive metal constitutes a battery. The most simple method of interpreting such an arrangement with regard to the "signs" of its parts electrically considered, is by remembering that the part of the zinc immersed is positive; the part out of the acid, together with the connecting wire and attacked electrode, is negative; the opposite electrode, where the chlorous element is eliminated, together with the whole of its platinum connection, as far as the surface of the liquid in the battery, is positive. The part immersed in the liquid of the battery is negative. This comes to the same thing as saying that the positive ion is liberated at the electrode in connection with the positive element of the battery, the negative ion at that connected with the negative element. It must be borne in mind, that the ions appearing at the two electrodes are not *absolutely* positive and negative towards one another. All that is known is that they are in the same relation with regard to sign, as are the elements of the battery by whose action they are separated; and that thus, with regard to sign, all we know on decomposing chloride of silver by means of a Grove's battery is that

Ag : Cl : : Zn : Pt.

That electric currents are established between the active and passive points of a metal, and that the positive current passes from the active to the passive part, is seen in the example of so-called passive iron. If clean iron be dipped into strong nitric acid, no evolution of gas occurs, and the iron is not acted on. If another piece of iron be first plunged into dilute nitric acid, and then into the strong nitric acid, the decomposition set up in the dilute acid is carried on in the strong acid. It is possible thus in one and the same acid to have two pieces of the same metal, the one of which is active and the other passive. On connecting the two, a current passes through the connector, just as if platinum had been employed instead of the passive iron. Nickel may by the same means be brought into the passive state, and a battery formed of elements of active and passive nickel. It is beyond the scope of this article to describe the conditions under which the passivity of iron is destroyed or preserved.

The power possessed by high tension or frictional electricity of effecting chemical change is very small in comparison with that of low tension or galvanic electricity; and in many cases where chemical change accompanies frictional electricity, it may be traced to the accompanying forces of light and heat.

If an electric spark be made to pass through an atmosphere of mixed oxygen, nitrogen, and water, the nitrogen combines with the oxygen in part and in part with the hydrogen, the two products so formed combining together.

If a spark be made to pass through water by means of exceedingly fine platinum points, minute bubbles of hydrogen and oxygen collect at the poles.

Mixtures of oxygen and hydrogen, or hydrogen and chlorine, are exploded on passing a spark through them.

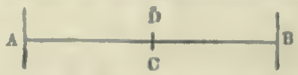
The following are examples of the formation of high tension electricity by chemical change:—

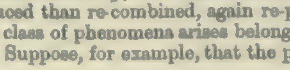
The insulated grate of a stove in which coal is burning is found to be negatively electrical. If hydrogen passes through a metal tube, and is then burned, the tube is found to be negatively electrical. If dry air and chlorine be passed through a thin copper tube, the latter becomes negatively electrical; if the product be then passed through a platinum tube, the latter becomes positively electrical.

With regard to the relative powers of low and high tension electricity to effect chemical change, it has been found that—"A wire of platinum and a wire of zinc, each 1/18th of an inch in diameter, placed 5/16ths of an inch apart, and immersed to a depth of 5/8ths of an inch in an acid consisting of one drop of oil of vitriol in four ounces of distilled water, at a temperature of 60° Fahr., and connected at their other extremities by a copper wire 18 feet long and 1/18th of an inch thick, yield as much electricity in about three seconds of time as a Leyden battery exposing a surface of 3500 square inches, charged by 30 turns of a plate-glass machine 50 inches in diameter in full action."

ELECTRODE. [Electro-chemistry.]

ELECTRO-DYNAMICS. In ordinary electricity, that fluid when developed takes a position of equilibrium, dependent on the conducting power of the medium on which it is disposed, on the non-conducting power of the medium by which it is enveloped, and on the law of force, whether of attraction or repulsion, between the elementary portions of electricity. The motions of electrised bodies are only results of the statical equilibrium of this fluid, and do not therefore belong to electro-dynamics. The mode of calculating such effects may be found under the head Electricity, Common. These effects are, moreover, of the same nature, whether the source of electricity be by means of friction, or by chemical action, as in the voltaic pile, the nature of the electricities in these cases differing from each other only in the mode of their production [Electricity]; but when the contrary electricities are no sooner produced than re-combined, again re-produced, and again re-combined, a new class of phenomena arises belonging to electricity as it were in motion. Suppose, for example, that the plate A is a constant source of positive electricity, the plate B in like manner a constant source of negative electricity of equal intensity; that A C, B C, are two conducting rods communicating with each; the electricities immediately combine when the conductors are made to touch at C, and for an instant the whole may be conceived to be in the neutral state, but A being the next instant replenished with positive and B with negative electricity, the same combination takes place over again, the same neutrality succeeds, and so on indefinitely. The rod A C B is in a different condition from one in its natural state, since electrical charges are continually pouring through it from A and B; and again it is in a different condition from an electrised rod, since we cannot at any moment say that it is charged positively rather than negatively. Hence we cannot infer that it should attract rather than repel an electrised ball D, since there is as much reason for one event as the other, and in point of fact we find that it neither will attract nor repel D. We have here a positive current of electricity issuing from A and a negative from B, and no effect of attraction or repulsion is produced on an electrised point as in statical electricity. How then is its state recognised? First by touch; for if we touch the rod A C B, a series of shocks is felt, the interval between two succeeding ones being inappreciable; and secondly, powerful chemical decomposition may be effected. [Galvanism; Electro-Chemistry.] But, thirdly, we may recognise it mechanically by presenting to A B another rod A′B′ under exactly similar circumstances, when the effects of the currents in A B, A′B′, will be recognised by the visible motions of the rods, provided they be free to move while their communication with the proper sources of electricity remains unbroken: for example, if their extremities be immersed in cups of mercury communicating with the constant sources of the positive and negative electricities. The laws of the mutual action of electrical currents constitute the science of electro-dynamics; and previous to its study it would be desirable that the reader should be acquainted with the construction and applications of the galvanic apparatus, the opposite poles of which afford the two constant sources (A B) of electricity which we have supposed. These will be found under the head Galvanism.

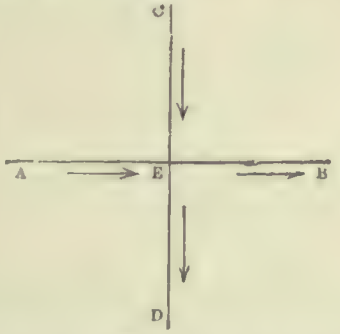




To discover the laws of the mutual actions of electrical currents we must have recourse to experiment. The apparatus required for the purpose is figured in books on physics, together with a description of the mode of performing the various experiments by which these laws have become known. [Electro-Magnetism.] The term *direction of a current* is convenient when speaking of more than one; for instance, the zinc end of the pile being a constant source of positive electricity and the copper end of negative, a rod communicating with wires connected respectively with these extremities will have a current of positive electricity from the zinc to the copper, and a negative current in a contrary direction; but as it is simultaneously permeated by both, when we speak of the direction of a current we shall understand that of the positive current to avoid ambiguity.

Two parallel currents which are directed in the same way attract each other, but when directed in opposite ways they repel.

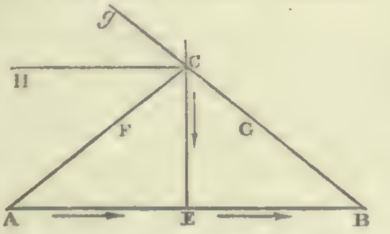
When rectilineal currents form mutually an angle, the species of action which they exercise may be thus defined: "Two portions of currents will attract if they are both approaching or both receding from the vertex of the angle which they form; but when one approaches and the other recedes from that angle, then they repel:" the same law holds in the limiting case of parallelism.



Let two currents cross each other, as A E B, C E D, and suppose the directions of the currents to be those indicated by the arrows in the figure; then, according to this law, the force between C E, E B, is repulsive; and that between C E, E A, attractive; if, therefore, A B is fixed, and C E D moveable, we ought to have C E tending towards A E, and for the same reason, D E tending towards E B; the rod C E D, therefore, has a rotatory motion impressed on it until it is placed parallel with A B: this is confirmed by experiment.

If we now consider two currents to form a very obtuse angle, one of them approaching, and the other receding from the vertex, we have repulsion; let the obtuse angle be increased to 180°, and in this extreme case the two currents merge into one: hence it follows that the consecutive parts of one and the same current exercise a mutual repulsion on each other.

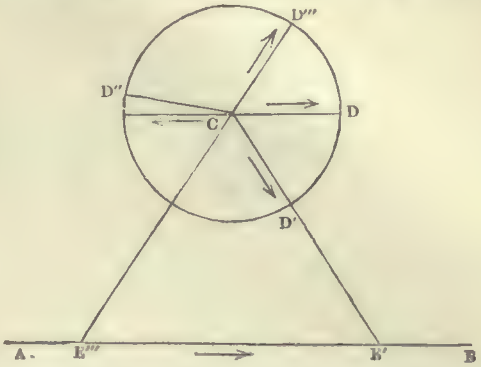
The actions exercised by a rectilineal current and by a sinuous current, which have generally the same direction and are terminated at the same extremities, are equal, the intensity of action being supposed the same in both cases; thus, if we suspend a moveable conductor between a rectilineal and a sinuous conductor disposed so as to repel the first, this, after a little oscillation about its mean place, will finally rest in the middle of the interval between the conductors.



Let us now consider the action of an indefinite current A B, on a terminated current C E, which is directed towards E; the direction of A B being that indicated in the figure.

The portion B E of the indefinite current repels E C, in consequence of the contrary direction of the current in the latter. Let us represent this force in magnitude and direction by $Cg = CG$; also A E attracts C E; the force may be represented by C F, similarly situated with C G; but Cg, the repulsive force of B E, is drawn without the angle B E C; and C F, or the attractive force of A E, must be drawn within the angle A E C. If we now compound the forces C F, C G, they will manifestly produce a resultant C H parallel to the indefinite current A B. Hence the terminated current will be urged by a force parallel to the other, and in a contrary direction; and by similar reasoning it is easily seen that if the direction of the current C E were contrary to that indicated by the arrow, or receded from A B, then the whole force in C E would be in the same direction as the current A B, and parallel to it.

Let us suppose C D to be a conductor moveable round an axis at C in the plane D D′ D″, and suppose the direction of its current to be from C towards D, and that of an indefinite conductor A B to be similar and parallel; then A B attracting C D will turn it round C into the position C D′, and the force on the angle C E′ B is then repulsive, and in C E′ A attractive; hence C D′ will further turn round, and the same direction of rotation will be continued in the upper semicircle; for the force is attractive in the angle D‴ E‴ B, and repulsive in D‴ E‴ A. Hence a continued rotation will be produced. This rotation will be in the contrary direction if we change the direction of the current either in A B or C D; or if, without changing the current, we transfer A B to the opposite side of C D: hence if A B be placed so as to meet the axis C, there will be no rotation; hence also if the terminated current be moveable round its middle point there will be no rotation, since both its halves tend to rotate in contrary ways. It is easy to analyse in the same manner the action of an indefinite conductor on a closed current by considering its action on each of the parts, the general effect being to bring the moveable conductor into a position of equilibrium in a plane parallel to the indefinite conductor.



Instead of a single closed circuit we may suppose any number of them connected together after an invariable manner. The action of an indefinite current will still tend to bring that system into a plane parallel to its direction. These systems have been called electro-dynamic cylinders and also canals of currents.

In consequence of the electro-chemical causes which are so widely diffused through the globe, electrical currents are generated, which give its polarity to the magnet, and which, as is well known, are sufficient to generate continued rotation of given currents.

It has been found by Ampère that the actions of similar conductors on points similarly situated are equal; and that a closed conductor exercises no action on a circular conductor moveable round a central axis.

In seeking for the true laws of elementary action of currents, a decomposition similar to that of the parallelopiped of forces may be employed; that is, for the action of an elementary current we may substitute the actions of the three sides of a parallelopiped terminated at the same extremities; for, as before stated, if we preserve the direction of the currents we shall not alter the action by substituting any sinuous for a plane conductor with the same extremities.

We will now show how the law of force between the elements of currents may be obtained, which, when once known, will reduce all the phenomena to mathematical calculation.

To determine the law of force tending to or from any element of an electrical current, when points of another current are taken at different distances but in a given direction:—

Let δs, $\delta s'$ be the elements of two electrical currents, of which the intensities are i, i', their distance a unit, and f the force mutually exercised in the line forming their middle points; hence $f = ii' \, \delta s \, \delta s'$.

Let $\delta\sigma$ $\delta\sigma'$ be portions of similar currents to the former, but of which the linear dimensions are ν times as great, and since their mutual distance is also ν times as great; this force is diminished in proportion to some function of ν, as $\phi(\nu)$: hence $f' = ii' \, \delta\sigma . \, \delta\sigma' . \, \phi(\nu)$.

$$\text{Now } \delta\sigma = \nu \, \delta s \qquad \delta\sigma' = \nu \, \delta s'; \text{ therefore}$$
$$f' = ii' \nu^2 \, \delta s \, \delta s' . \, \phi(\nu).$$
$$\text{Hence } \frac{f}{f'} = \frac{1}{\nu^2 \phi(\nu)}$$

We should have the same proportions if, instead of elements, we took conductors of any lengths but still similar, for this is equivalent merely to integrating the above expressions after decomposing the forces in fixed directions; and since we have experimentally in this case $f = f'$, it follows that $\phi(\nu) = \frac{1}{\nu^2}$; that is, the law is the inverse square of the distance, as in statical electricity; but we must observe that the directions of the currents are here supposed to make given angles with the joining line ν.

The following theorems are taken from Mr. Murphy's 'Electricity,' to which we refer for the demonstrations, which are by no means difficult to persons a little acquainted with the differential and integral calculus.

Let a right line ν join the middles of the elements δs, $\delta s'$ of two currents, being inclined respectively to those elements at the angles θ, θ', the planes of which angles are mutually inclined at an angle ϕ, and let ρ, ρ' be the intensities of the currents; the mutual action of these two elements will then be represented in all cases by the formula

$$\frac{\rho\rho'\,\delta s\,\delta s'}{\nu^2}\left\{\sin\theta,\ \sin\theta'\cos\phi - \tfrac{1}{2}\cos\theta\cos\theta'\right\}$$

$$= \rho\rho'\,\delta s\,\delta s'.\ \ -\frac{1}{\nu}\tfrac{1}{2}\frac{d}{ds}\left(-\frac{1}{\nu}\tfrac{1}{2}\frac{dr}{ds'}\right)$$

Let R Θ, R_1 Θ_1 be the final values of ν and θ for any given current of which δs is an element, $\delta s'$ remaining as before; then the total action of this electrical current on the element δs in the direction of its length will be

$$\tfrac{1}{2}\,\rho\rho'\,\delta s'\left(\frac{\mathrm{Cos}^2\,\Theta^1}{R^1} - \frac{\mathrm{Cos}^2\,\Theta}{R}\right).$$

This may be easily deduced from the preceding formula.

Hence an indefinite current, for which R, R_1 are infinite, exerts no longitudinal action on $\delta s'$; only a normal force. This coincides with what has been before shown for the action of an indefinite current on a terminated conductor. The same property holds true for a closed current, since in this case $\Theta = \Theta_1$ $R = R_1$.

From hence it is easy to find the total action of a fixed current, or a moveable rectilineal current.

The action of a closed current, or an element of another current, which is turned in all possible positions round its middle point, lies in an invariable plane.

The mutual action of two small closed conductors, containing areas, λ, λ', the centres of which are at a distance ν, exercise on each other a force directly as the plane areas, and inversely as the fourth power of the distance.

The action of a uniform canal of currents indefinitely extended in one way varies inversely as the square of the distance of its extremity from the element acted on, and directly as the sine of the angle which that distance forms with the element, and is in a direction perpendicular to the plane passing through the element and the extremity of the canal.

When two uniform and indefinite canals of currents act on each other, the canals being supposed terminated at one extremity only, the resultant is in the line joining their extremities, and the force is inversely as the square of this line: hence the action of finite canals may be easily estimated, as being the difference between two indefinite canals. With respect to the nature of the force, it will be attractive or repulsive as before described. The simplest mode of observing the actions of a canal of closed currents is by twisting a wire in the form of a helix having but small intervals between the successive convolutions, the action of each portion of the helix being then very nearly the same force as that of a portion of a circle or closed current.

Ampère imagined an ingenious manner of calculating the actions of any plane closed conductors. Conceive one such to be divided into an infinity of small compartments by right lines parallel to the rectangular axes of co-ordinates, and the periphery of each compartment to be traversed by currents, in the same manner as the whole curvilineal side which encloses the area; then it is easily seen that all the internal sides of the compartments, being traversed by two currents in opposite directions, will have no electro-dynamical action, and therefore the sole remaining current is that which circulates in the periphery of the given figure; but by this division into compartments we can calculate the mutual actions of the two closed conductors from the very simple law which we have already given for the action of small closed conductors on each other.

Voltaic conductors, of which the centres of gravity are supported, undergo terrestrial action, similar to that produced by a canal of currents. We should infer, by the position which the moveable conductor takes, that the direction of the terrestrial currents is nearly from east to west, having the north magnetic pole situated on their right.

Since the action of closed currents on an element of a conductor is perpendicular to that element, hence a straight conductor fixed at one extremity, and free to move in a horizontal plane, will receive a continued rotation from the influence of the currents of the earth; but if the conductor were supported by its centre of gravity, it would be brought by their action into a fixed plane, and an electro-dynamic cylinder would come into a position perpendicular to that plane.

All these results of theory are confirmed by experiments, and are shown in the lecture-rooms of gentlemen who profess this branch of science.

With respect to the quantity of the galvanic current, Ohm in 1827 advanced the following formulæ:—1. For a conductor, into whose extremities the two electricities flow with a given tension. Let A be the electrical tension; K, the conducting power of the wire or other conductor; w, the surface of its transverse section; L, its length; Q, the quantity of the current, then $Q = \frac{AKW}{L}$. 2. For a simple galvanic circuit: Let A be the electro-motive power of the circuit (or the tension?), R, the resistance which the current meets with in the circuit itself. This is the resultant of the following individual resistances: a, resistance of the two metallic plates which the current has to traverse; b, resistance of the liquid through which the current passes. To this, Fechner and Poggerdorff add, c, resistance of transition, or the resistance which exists to the passage of the electric current from the metal to the liquid and conversely. Also, let r be the resistance of the conductor which unites the two metals, and Q, the quantity of the electric current which enters it; then $Q = \frac{A}{R+r}$; therefore, $A = Q\,(R+r)$. 3. For the galvanic battery: n, denoting the number of united simple currents $Q = \frac{nA}{nR+r}$. When the resistance, r, of the conductor which closes the circuit is inconsiderable in comparison with the resistance R, in the individual circuit, it nearly vanishes in the formula, and there remains $Q = \frac{nA}{nR} = \frac{A}{R}$, that is, the quantity of the current is the same, whether it proceed from one pair or from several. But if the resistance of the conductor which closes the circuit be considerable, as from the interposition of water, &c., then Q increases considerably with the number of pairs, because then $\frac{A}{R+r}$ gives a much smaller quotient than $\frac{nA}{nR+r}$. ELECTROLYSIS. [ELECTRO-CHEMISTRY.]

ELECTROLYTE. [ELECTRO-CHEMISTRY.]

ELECTRO-MAGNET. [ELECTRO-MAGNETISM.]

ELECTRO-MAGNETIC MACHINES. [ELECTRO-MOTIVE MACHINES.]

ELECTRO-MAGNETISM. The first important discovery in point of time, which laid the foundation of this new science, was made by Professor Oersted of Copenhagen. By reference to the article ELECTRO-DYNAMICS, it will be seen that when the wires which communicate with the poles of a galvanic battery are connected by a conductor or by being brought into contact with each other, the opposite electricities thus continually made to combine acquire a power of action on another conductor under similar circumstances, though latent with respect to common electrical action; but this discovery of Ampère was preceded by that of Oersted, who found that the electrical current thus generated acted upon a magnetised bar, and tended to turn it round as if exercising a tangential force. Before this time a connection between electricity and magnetism had been suspected, or rather believed, by Franklin, Beccaria, and others, from the well-known circumstance that the poles of the compass-needle had been frequently reversed during thunder-storms, and that the same effect could be produced by electrical discharges. In most experiments which were then made these discharges were unnecessarily strong; but to Oersted's discovery, followed up as it has been by Ampère, Faraday, Barlow, Arago, &c., we must ascribe the source of those accurate data by which the actions of the earth on magnets, of magnets on each other, of conducting wires on magnets, and of the earth on conducting wires, are reducible to similar and simple principles of action.

When a magnetic needle is placed near a conducting wire in the plane of the magnetic meridian, and the battery is powerful, it is observed that the needle will turn round, placing itself at right angles to the direction of the current; the same effect, which we have seen in the preceding article, would be produced by the same conductor on a canal of currents. If we suppose that a man with his face turned to the needle is himself the conductor, with his feet at the positive pole, the north pole of the needle will turn towards his right. This must be understood as only meant to illustrate the direction of rotation.

In order to discover the law of action of a current on a magnetic element, Biot and Savart used a small magnetic needle, guarded from the agitations of the air, and having the action of terrestrial magnetism neutralised by a bar, thus subjected only to the immediate action of the conductor. Having acquired the position indicated by Oersted, the times of its small oscillations were observed, which we know by the principles of Dynamics must be inversely proportional *cæteris paribus*, to the square root of the accelerating force impressed. By observing the times in which, for instance, ten oscillations of the needle took place at different distances, it was deduced without difficulty, that the electro-magnetic force exercised by the whole conductor was inversely as the distance of the needle from the conductor; this of course supposes that the current may be regarded as indefinite, compared with the dimensions of the needle. Hence it easily followed, as was shown by Laplace, that the force exercised by each element of the conductor on the magnetic needle must, like all known forces, vary inversely as the square of the distance; and Biot showed that, when the distance was given, the force was then proportional to the sine of the angle formed by each element of the current with the right line joining the middle of that element with the middle of the needle.

It has been shown by means of the multiplier that the electrical intensity of the current at different points of the same conductor is constant. We may observe that the principle of the multiplier consists in bending the wire in the form of a helix, but returning upon itself so as to form a closed circuit, the wire being covered with silk to prevent communications at the crossings; the action of such a spiral being similar to that of closed circular currents equal in number to the spiral convolutions.

It was afterwards found that the magnetic needle of the multiplier could be acted on by electrical discharges from a Leyden jar; and Mr. Faraday showed conclusively that, with the condition of time, ordinary electricity can produce a continued deviation of the needle; this condition he fulfilled by making the electricity pass through imperfect conductors.

Arago observed that small fragments of soft iron were attracted by the conductor of the galvanic pile, and the same current imparted permanent magnetism to small needles of steel. The needle should be placed perpendicularly to the joining wire or current, or, which is better, be introduced in a helix, the discharge of the current through which instantaneously magnetises the needle.

Nobili observed that needles placed between the isolated spires of a plane spiral of copper wire were, by an electrical discharge, magnetised in opposite ways, when near the centre and when near the circumference. Savary also observed that when needles were placed horizontally with their middle points vertical over a horizontal current and the needles perpendicular to the direction of the current, they were differently magnetised according to their distances. These experiments he has varied relatively to the length of the needles, the length and diameter of the conductor, &c.

The magnetising force of the current is transmitted without sensible loss through isolating media, as glass, wood, &c., but is much altered by the interposition of conducting plates, a result similar to the development of ordinary electricity by the influence of electrised bodies. Thus—a large plate interposed between the conductor and the needles weakens the magnetising effect of feeble discharges, while it augments strong ones: and for a given charge, a thin and a broad interposed conducting plate may produce contrary effects, and with a certain determinate breadth the effect would be unaltered, and in general the two surfaces of the same plate exercise contrary actions. (Savary.)

When a bar of soft iron, bent in a horse-shoe shape, is encompassed by a helix covered with silk and always turned in the same way, it may be made to receive a powerful magnetism under the influence of a current through the helix discharged from a voltaic battery. In this way electro-magnets have been formed capable of supporting a ton weight and upwards. The magnetism of the soft iron under the influence of the voltaic current, attains its maximum in a few moments, and ceases immediately when contact between the helix and the battery is broken. On reversing the direction of the current through the helix the polarity of the electro-magnet is also reversed. It is remarkable that the molecular action which we know must take place in magnetising a bar of soft iron has the effect of increasing its length, and at the same time causing it to emit an audible sound, the note being such as would be produced by striking one end of the bar. The same note is also produced on breaking contact with the battery when the bar returns to its original dimensions. If these molecular movements be quickly alternated by making and breaking contact in quick succession, there is an elevation of temperature in the bar which is quite independent of the heat of the conducting wire caused by the current.

The great use which is made of the electro-magnet in telegraphy [TELEGRAPH] has led to considerable research as to the most favourable conditions for forming it. According to Lenz and Jacobi, when the voltaic current is of uniform strength the magnetism induced is directly proportional to the number of coils on the bar, which coils may be distributed over its whole length or be accumulated towards its two extremities. Nor is the effect influenced by the diameter of the surrounding coils, for although the induction diminishes as the distance of the magnet from the wire, yet the induction produced by the increased length of the wire in the circumference of the coil is augmented in the same proportion. The thickness of the wire is a matter of indifference, the energy of the magnetism being *cæteris paribus* proportional to the strength of the current, it being directly as the electromotive force, and inversely as the resistance of the circuit. The retentive power of the magnet, like the attractive power of electricity, increases as the square of the intensity of the magnetism. The magnetic effect of a solid bar is proportional to its surface; in cylindrical bars it is as the square of the weight. Now as bundles of insulated wires expose a larger amount of surface than a solid bar, they are capable of a higher magnetic result than a solid bar of equal weight. It is also stated that the only advantage of long bars over short ones is the removal to a greater distance of the two opposite poles from each other.

The discovery of the currents produced by volta-electric induction is due to Mr. Faraday. With about 203 feet of copper wire he formed each of two helices, and twisted them about a cylinder of wood, making one in communication with a galvanometer and the other with a powerful voltaic pile. The moment the communication was established, the galvanometer deviated; then, after some oscillations, returned to its place, and again deviated the instant this communication was broken: hence the directions of the inducing and induced currents are contrary, while that generated at the interruption of communication or cessation of the inducing current is directed the same way with the latter.

The same philosopher has also succeeded in producing currents by the influence of magnets, his experiments with the great magnets of the Royal Society proving most manifestly the disengagement of electricity by the influence of ordinary magnetism. The extraction of the electrical spark from the magnet, as also the continued rotations produced by terrestrial magnetism, are well-known phenomena. [MAGNETO-ELECTRICITY.] The theory of Ampère, which supposes electrical currents to exist round the component particles of magnetised substances, and round the mass of the earth, is perhaps the most satisfactory explanation yet given of the cause of magnetic action, and has been greatly strengthened by the discoveries of Faraday on electro-magnetic induction, by which many objections that had been urged against this theory are removed.

The varied phenomena of electro-magnetism require a good deal of delicately constructed apparatus, a knowledge of the subject, and much careful manipulation, for an account of which we may refer to almost any competent work on natural philosophy.

ELECTRO-METALLURGY. The chief object of this branch of applied science is the deposition of a thin metallic layer on the surface of some other body prepared for its reception; the outer layer being intended generally (but not always) for one of three purposes—the decoration, the protection, or the imitation of that which lies beneath. The mode of proceeding assumes different forms, according to the purpose in view. The names *Electrotype, Galvanotype, Voltatype, Voltagraphy, Galvano-Plastics, Electro-Plating and Gilding,* have been all applied in a somewhat confused manner to different modifications of the art; but we agree with Mr. Smee, that it would be convenient to adopt the term *Electro-Metallurgy* as a general one, including all or most of the varieties.

Under the article GALVANISM will be found an account of the principle of what are termed *batteries*, or arrangements for generating and sustaining electro-chemical currents. If the wire connected with the zinc element of a compound battery have a plate or surface of any conducting substance attached to it, moulded into any form, or having any design or pattern cut upon it, while the other wire terminates in a copper plate of equal surface with the former, both being placed near and parallel to each other, but not in contact, and be immersed in a saturated solution of sulphate of copper, this solution will undergo decomposition; the metallic copper will be slowly and equally deposited on the plate, and will form an exact counterpart or *cast* of the form or pattern. It is the power thus obtained of copying in metals deposited by electrolytic action any form or pattern which is made the negative surface of a voltaic circuit, which constitutes the basis of electro-metallurgy: and it now remains to explain briefly by an example the mode of manipulation to be employed.

Let the object to be copied be a small *bas-relief* of about six inches by four, executed in a material such as marble, ivory, or plaster of Paris, which will admit of a wax mould being taken from it by the usual processes: to do this, the original, if of plaster of Paris, must be well oiled at its surface, to prevent the wax from adhering to it; but the oil must be allowed to soak into the plaster: the wax, which should be of the finest white kind, must be poured on, well melted, and the plaster should be previously warmed to prevent the wax from being suddenly cooled by the contact before the whole surface is covered with it: when cold, the mould may be detached from the original without injury to either. That this mould may be employed as the conducting-plate of a voltaic circuit, its surface must be rendered *conducting*, which the wax itself is not: for this purpose the surface is to be covered over with the finest powdered plumbago, equally and lightly rubbed in by means of a camel-hair pencil; and the success of the operation depends on the face of this mould being equally covered with the plumbago, the back and edges remaining as they were.

An earthenware or wooden vessel of any convenient form is chosen, capable of holding the mould and a copper plate of the same size at the distance of half an inch from it, so that they may be quite immersed in the solution of sulphate of copper: it is better if the mould and plate be vertical in the vessel. The copper plate must have a wire soldered to its upper edge, for the purpose of connecting it with that of the battery, both plates of which should consequently be provided with binding-screws, to allow of these connections being made and broken at pleasure. The wax mould must also be connected with the zinc element of the battery by an intermediate wire, and care must be taken that this wire be in perfect contact at the point of union with the conducting surface on the wax mould; while it obviously must not be so connected as to injure that surface or disfigure it: the plumbago accordingly must be accumulated round the part where the wire is put into the edge of the mould, and continued to the front in a narrow well-defined band.

The mould and the plate being placed parallel and very near to each other, face to face, but not in contact, they must be retained in that position in any convenient manner; but care must again be taken in so doing that there is no contact by any conductor between them. The vessel may then be filled with the saturated solution of sulphate of copper and the wires connected with the battery, the precise size and form of which are immaterial. The whole must now be left undisturbed for from twenty-four to thirty-six hours, at the end of which time, the mould, being detached from the battery and withdrawn, will be found covered over with pure bright metallic copper, rough on the outer surface; but when separated from the wax by gently heating, it will, if the operation has been successful, present a perfect copy of the bas-relief, every line of which, to the most delicate markings, will be found transferred to the metal with more precision and delicacy than could have been produced by a cast made with the copper in a state of fusion. Perhaps few facts connected with the laws of aggregation of homogeneous matter are more striking than the one under consideration, and few facts indirectly afford a more remarkable instance of the chemical divisibility of matter. The infinite gradations of tint produced on a silvered surface coated with vapour of iodine, and acted on by light, in the process of the Daguerreotype, can be copied with the most perfect accuracy by electro-metallurgy; and it must be remembered that these gradations depend solely on variations in the molecular arrangement of a coating of mercury, with which the silver has been amalgamated, by exposing it to the vapour of that metal, too thin to be measured, and defying microscopic power to detect.

In order to admit of the copper during its deposition arranging itself so as to assume a malleable or true metallic texture, it is necessary that the electrolytic action be not too rapid, accordingly the battery should be weak in its action. Among other precautions which should be mentioned is that of not reversing the connections, if at any time during the process they should be broken, to allow of the progress of the work being ascertained; for if this should be done, the current being reversed, the copper previously deposited on the mould will be re-absorbed. And in order to keep up the equable and constant deposit which is necessary to ensure homogeneity in the metallic deposit, the liquid solution, both in the vessel containing the mould and in the battery, must be kept constantly saturated by the addition of fresh solid crystals of sulphate of copper: but in putting these into the former vessel, care must be taken not to let the crystals touch the mould; and indeed the fluid in this vessel should not be disturbed if possible during the process, which is easily insured by placing a sufficient quantity of the salt in the vessel before the commencement of the operation.

The *electrotype*, as the above process was called, was first indicated by Professor Daniell, of King's College, shortly after the invention of the constant battery. He observed that copper deposited upon a plate of platinum produced a coherent sheet, in which the lines and irregularities on the platinum were correctly reproduced by the copper. In 1839, Mr. Spencer, and Mr. Jordan in this country, and M. Jacobi, of St. Petersburg, announced their invention of that process, at least in its main features, as above described. The electrotype at once became a popular pursuit. Thousands of amateurs occupied themselves in copying medals, seals, plaster casts of medallions, vegetable objects, such as twigs, fruit, leaves, seeds, and even insects; but the subject was too suggestive to be neglected by manufacturers, and accordingly, in the following year, Mr. Elkington, in England, and M. Ruolz, in France, began to apply the voltaic battery on an extensive scale to the arts of plating and gilding. Innumerable patents have been granted for new processes, or variations of old ones, and the electric current came to be used not only for depositing copper, gold, and silver from their solutions, but also zinc, tin, lead, platinum, and nickel. Many other metals have also been reduced from their salts by its means when required for special purposes. Original inquirers at home and abroad, have lent their aid in investigating the subject, and the result has been a wide extension of electro-metallurgy to other arts, such as stereotyping and nature-printing; it has been used for making moulds for the foundry, for reproducing printed characters, copper-plates, wood engravings, rollers for the calico printer, copper-plate engravings, daguerreotype pictures, &c. Such are a few of the varied applications of the art, and we will now give an example of one of its important applications, and connect it with some general details.

The electrotype has been used for multiplying large copper-plates, such as those engraved for the Art Union, for which purpose a matrix is first produced, in which all the sunk lines of the original plate are represented in relief in the copy or matrix, and this is used as the parent of succeeding copies. In forming the matrix, a slip of copper is soldered to the original plate, the back of which is covered with a resinous varnish to prevent it from receiving a deposit of the reduced metal, and thus prepared, the plate is lowered vertically into a saturated solution of sulphate of copper, and connected with the negative pole of a voltaic battery, which may consist of three or four of Smee's or Daniell's cells. Connected with the positive pole of the battery is a sheet of copper, equal in size to the one to be copied, and placed parallel to it. The solution immediately begins to be decomposed; metallic copper is deposited on the surface of the negative plate, while an equivalent quantity of copper is dissolved from the positive plate, by which means the solution always retains an equal quantity of sulphate of copper. The process requires watching at the commencement, to see that the deposit is uniform, for should the negative surface be soiled with grease or resin, no deposit will take place in those parts. The solution also requires to be frequently agitated, to prevent it from becoming impoverished about the negative plate, and too much saturated about the positive plate, for should such occur, the unequal density of the solution will cause currents to set in, whereby vertical grooves and striæ will be formed on the back of the sheet of deposited metal. To prevent these effects, the plates are sometimes supported horizontally in the bath, the negative plate being undermost, but in such case the positive plate must be wrapped in flannel to prevent the small particles of metal, which are constantly leaving it, from falling upon the lower plate. When the deposit is sufficiently thick, it is detached at the edges, and can be easily removed.

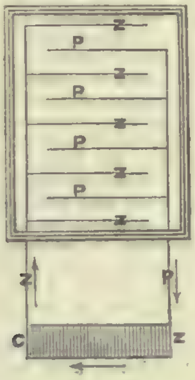
The texture of the deposited plate depends upon four circumstances: 1, the strength of the battery; 2, the degree of concentration of the solution; 3, its temperature; 4, the relative size and position of the two electrodes. As these conditions vary, the deposit may be as hard and brittle as steel, as soft and flexible as lead; of a crystalline texture, and even pulverulent. M. Boquillon has found, other things being equal, that if the positive electrode be of larger size than the negative, the deposit will be crystalline, and if the difference between the two plates be considerable, the deposit may be pulverulent. The contrary effect takes place, if the positive electrode be the smaller of the two. Similar results may arise from an increase in temperature. In the case of the solution, if it be completely saturated, the deposit will be hard and brittle; if less saturated, it will be more flexible, and if weak, it will be spongy, crystalline and even pulverulent. These generalisations, however, do not apply to all the metals, for many of them are thrown down from their solutions in a crystalline form, whether the deposition be made quickly or slowly. Silver behaves in this way when separated from its nitrate, and lead from its acetate and nitrate. Gold and platinum do not form coherent plates from solutions of their chlorides, but it sometimes happens that where the solution of a simple salt fails, good results may be obtained by the use of certain double salts of the same metal, with potash or soda: thus, the double cyanide of gold and potassium is used for gilding, and a similar salt of silver for silvering.

Steel plates do not admit of being copied in the same manner as copper-plates, since the steel and the sulphate of copper solution act chemically on each other, but by first electrotyping the steel plates in silver, which can be deposited without injury to them, and using the silver as a matrix, a copper fac-simile of the original plate can be obtained.

In copying objects which would be injured by immersion in the metallic solution, we have seen that the early electrotypists took casts in wax, and made the surface conducting, by rubbing it over with finely divided black-lead. Casts are now made in fusible metal, stearine, or gutta-percha; in the last case, two parts of gutta-percha, and one part of marine glue should be used, the glue to be melted at a gentle heat and incorporated with the fragments of gutta-percha. In taking a cast, the paste is to be applied soft, and with a gradually increasing pressure. In some cases, an impression of the object to be copied is obtained in sheet lead, by the application of a strong pressure, as for example, in what is called *nature-printing;* suppose a frond of fern is the object to be copied, this is placed between a plate of steel and one of sheet lead and so passed between a couple of steel rollers in a press. The soft lead receives the markings of the plant, so as to indicate its structure very minutely, and from this leaden impression a copper deposit or matrix can be formed, from which other electrotype plates are procured, well adapted for printing. When natural objects, such as leaves, flowers, insects, &c., have to be coated with metal, they are made conducting by being immersed in a weak solution of phosphorus, in bi-sulphide of carbon, or in ether, allowing the solvent to evaporate, and then plunging the object into a solution of nitrate of silver: the phosphorus reduces upon the object a very thin film of silver, which enables it to receive the deposit from the battery when placed in a metallic bath.

In copying small objects, a separate voltaic battery is not required, since the depositing cell may itself be converted into a voltaic couple; for example, an arrangement may be extemporised by means of the chimney of an Argand gas-burner, closed below by means of plaster of Paris, and supported in a vessel containing the sulphate of copper solution. The lamp-glass is to contain dilute sulphuric acid, and also an amalgamated zinc rod. From this rod proceeds a wire, which supports at its other end in the copper solution the mould or medal which is to be electrotyped. Crystals of sulphate of copper should be suspended in the upper part of the solution to keep it saturated.

Surface-Deposit, in Electro-Plating.—In the common manufacture of table-plate the articles are either made of standard gold or silver, or have a surface of these costly materials laid upon a foundation of cheaper metal; and it is as an improved mode of applying the gold or silver that the electro process has been chiefly introduced. Messrs. Elkington, of Birmingham, have obtained considerable celebrity for their electro-plated and gilt articles. The metal employed by them as the basis is a hard, white alloy of copper, nickel, and zinc, and fusible only at a high temperature; but silver can be readily deposited on brass, copper, bronze, and German silver. If the article is to be produced by stamping or by brazing, the alloy is rolled into thin sheets, which are worked up into form by the stamping-press or the hammer. [CHASING OF METALS.] But when the article is to be cast (which the more elaborate patterns generally are) a wax model is prepared, from which is made a brass cast, or "pattern," and this is carefully worked up by chasing-tools to the proper fineness and delicacy of detail. From this brass pattern is made a sand-mould; and in this sand-mould the article itself is cast in the alloy or white metal. This is made chemically clean by boiling in an alkaline solution, or heating to redness in a muffle, washing, and brushing with sand, and dipping in nitric acid, in order to prepare it for the reception of the silver; for it is an important object in electro-gilding, silvering, and zinking, to obtain a firm adhesion between the newly deposited metal and the object to be covered. In electrotyping, however, the reverse is the case, for adhesion between the deposit and the mould would be fatal to success. In order therefore to be able to detach the metal, it is customary to expose a newly polished article to the air for twenty-four hours before placing it in the depositing cell. In the case of electro-gilding and plating, when the object has been made chemically clean, it is immersed while wet in the silvering bath, represented in plan in the following figure, in which C Z is the battery, P P are rods connected with the negative pole, to which rods the copper wires for holding the articles to be plated are twisted: Z Z are silver plates attached to the positive pole. The silvering solution contained in the bath may be prepared by dissolving cyanide of silver in a solution of cyanide or of ferrocyanide of potassium, although in some cases solutions containing hyposulphite or sulphite of silver are used. A good working solution should contain $\frac{1}{30}$th of its weight of silver, but there is an inconvenience attending the use of cyanide of potassium, arising from the formation of carbonate of potash, which accumulates and interferes with the regularity of the process. If, however, cyanide of calcium be used, an insoluble carbonate of lime is formed, which sinks as fast as it is produced. The plated articles have a dead white or chalky surface, but may be burnished to a brilliant lustre. If, however, a small portion of bisulphide of carbon be added to the bath, the deposited metal has the lustre of polished silver. The thickness of the deposit is regulated by weighing the articles before they are placed in the bath, and once or twice during the process. A deposit of 1¼ to 1½ oz. of silver per square foot of plated surface is about the thickness of ordinary writing paper, and is said to wear well. The solution requires frequent stirring, and the strength of the battery is regulated by the experience of the workman.



In electro-gilding, the article is made chemically clean, and placed in a bath of cyanide of gold dissolved in cyanide of potassium. The gilding solution does not usually contain more than 1 per cent. of gold. M. Ruolz brings the cyanide of gold into solution by means of the ferrocyanide or the ferridcyanide of potassium; he has also used the double sulphite of gold and soda, and some other similar compounds. A solution of the double chloride of platinum and potassium in caustic potash has been used for electro-platinising. Patents have been taken out for electro-deposits of silicium, titanium, tungsten, chromium, and molybdenum. Indeed attempts, more or less successful, have been made to obtain deposits of nearly all the metals.

Solid-deposit in Electro-plating.—In this case the mould is formed of a melted composition of glue and treacle, which has, when cold, sufficient elasticity to enable the pattern to be removed from it with facility, however much "undercut" the device may be. From this elastic mould a cast is taken, in a peculiar waxen composition; and this cast, when made conducting, is suspended in a tank containing a solution of sulphate of copper. A layer of copper is then deposited on the surface of the model, of such a thickness that when the waxen model is melted out from within it, the copper may be able to retain its shape unsupported. The result is, that the *inside* of the copper shell represents a mould of the *outside* of the article to be manufactured. The exterior of the copper is protected by a resisting or non-conducting composition, and it is then suspended in a tank containing a solution of silver (or gold, as the case may be); the galvanic current causes the deposition of the gold or silver on the inside of the copper mould; deposition on the outside being prevented by the resisting composition. When a sufficient thickness of the precious metal is thus obtained, the copper mould is exposed to the action of an acid, which gradually eats it away without injuring the gold or silver beneath, and the result is the production of a vessel or ornamental article of pure silver or gold, of the same pattern as the original wax model.

Electro-zinking.—A solution of sulphate of zinc may be used for depositing that metal on iron, much in the same way as the sulphate of copper. Only a feeble current is required, and the operation may be performed on a large scale. In this way the iron links of the Charing-Cross suspension bridge which go into the abutments on each side the river were coated. Each link is 24 feet in length.

Electro-deposit, as a protection or as an ornament.—The deposition of a thin metallic layer on a body prepared for its reception being thus rendered practicable, the applications of the method have become very numerous. It is in most cases as a protection, as an ornament, or as a copy or type, that these applications are intended.

As a protection against damp, &c., Mr. Dent has proposed electro-gilding for chronometer springs, instead of the usual method of "blueing," which he thinks affects their elastic force. A similar suggestion has been made for protecting magnetic bars and needles by the same means. It is surprising how admirably natural objects can be preserved by a metallic coating, and yet preserve all their characteristics. In this way even the exquisite framework of the insect's wings is exhibited almost as distinctly as in the natural state. Mr. Smee says ('Elements of Electro-metallurgy,' p. 222), "The beauty of electro-coppered leaves, branches, and similar objects is surprising. I have a case of these specimens placed on a black ground, which no one would take to be productions of art. . . . When I state that the numerous hairs covering the leaves of a *melastoma*, and even the delicate hairs of the *salvia*, are all perfectly covered, the botanist must at once admit that these specimens have rather the minuteness of nature than the imperfections of art."

In the preservation of all such fruits and vegetables as apples, pears, gourds, grapes, cucumbers, and potatoes, by electro-coppering, a pin is inserted before the immersion, and on this pin being afterwards removed, the hole left by it furnishes an outlet for the sap and moisture from within; and it is found that in many cases the inside dries up completely without deranging the shape of the copper envelope. Ornamental baskets, whether made of wicker or of wire, are coated in a similar manner. So likewise are lace and other articles made of woven fibres. Indeed, should a taste for productions of this kind spring up, the means are at hand for extending the art almost indefinitely; for by a preliminary steeping in a solution of phosphorus, or some other conducting agent, almost any substance may be brought into a state to receive a deposition of metal in a delicate film; and this film may be of copper, silver, gold, platina, or nickel. Porcelain and earthenware might without much difficulty be brought under similar operations.

Electro-deposit as a means of copying. Examples have already been given of this branch of the art; and we may here remark, that the electro-process has been recommended not only for copying engravings, but for making the copper-plate itself on which an engraving is to be executed. The copper-plates prepared for engravers generally contain a small portion of other metals, which render both the engraving and the etching somewhat uncertain: by the substitution, therefore, of plates produced by electro-deposition, in which the copper is quite uncontaminated with other metals, an advantage is anticipated. To produce these plates, a copper-plate is prepared in the usual way and suspended in a copper solution, by which a film of any desired thickness may be produced; and by a previous adjustment of the plate, the new portion may be separated from the old in the form of a distinct plate, susceptible of after-preparation for the engraver. Or, the copper-plate, instead of being made by deposition upon another plate of the same material, may be produced on a flat surface of wax or plaster properly prepared.

Galvanic etching and engraving. The voltaic current may be used for biting in the plates of the engraver instead of dilute nitric acid as usually employed. For this purpose both sides of the plate are covered with engravers' varnish, and the artist etches with a fine point the design on one of the surfaces, cutting through the varnish so as to expose the metal beneath. The plate is then connected with the *positive* wire of the battery, and on completing the circuit the oxygen and acid set free on the surface of the plate will attack those portions which have been laid bare by the tool of the engraver. As a plate etched in the common way is treated with the acid three or four times, to produce different grades of tint; so is likewise the plate etched by the galvanic method. Mr. Smee says that "the advantages of galvanism for etching are, the absence of poisonous nitrous fumes, which are evolved in the ordinary process; the greater uniformity of action which takes place than when acids are used; and the rapidity of biting, which may be regulated to the greatest nicety. The lines may be of any depth, and are sharper and cleaner than when acid is used; and lastly, no bubbles are evolved, which the engraver well knows are apt to tear up the ground, or to cause unequal action."

The terms *Electrotint* and *Glyphography* have been applied to two methods of etching by galvanism, in which the device is produced in rather a peculiar way. The methods are adapted, one for plate-printing, in which the design is in intaglio; and the other for surface-printing, as in common typography. For the former of these two methods, a paint or pigment is used, possessing the properties of working freely, laying on without spreading, and resisting the action of sulphate of copper: a composition of white wax, lard, lamp-black, olive oil, and turpentine, is said to answer well for the purpose. The plate employed is not of copper, but of some mixed metal presenting a white surface, such as one of the modern kinds of German silver. Brushes made of fitch, hog's hair, camel's hair, and sable hair, cut at the ends to various shapes, are employed; as also points of wood, ivory, and metal. The artist sketches his design on the dull white surface of the plate, and then paints the subject in full by means of the brushes and composition. All the parts which are to be white in the impression are left uncovered by the paint, either by handling the brush so as to avoid them, or removing the paint from them by a cork stump or other means; the kind of stroke and the thickness of the paint are made to depend on the depth of the shade in the picture. When the picture is finished, it is coated with black lead, and exposed to the electro-coppering process, by which a plate is produced fit for working in the copper-plate press, having the lines of the device marked in intaglio or sunken.

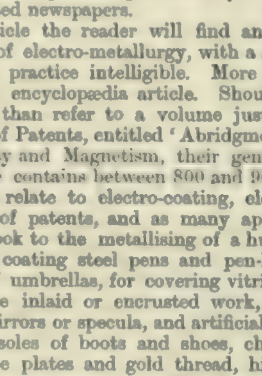
In the surface printing method, the paint or composition is so laid on as to cause a series of hollows in the electrotype deposit sufficiently deep to prevent being inked by the printer's inking roller; in other words, all those parts which are to be black in the impression are left untouched on the plate—a plan directly the reverse of the former. In order to aid the artist in producing the required effect, he uses a white paint on a black ground; the metal plate may be blackened by hydrosulphuret of ammonia, or by other agents; and a white paint may be formed from a mixture of sulphate of lead, white wax, lard, and olive oil. The mode of pencilling is entirely different from that adopted in the former case, and, as would appear, more difficult; for the artist has to avoid with his pencil all the parts which are to form the device or inked part in the impression. When the plate is finished it is coated with black lead, and immersed in the sulphate of copper; whereby a plate is produced fitted for surface-printing.

Minor improvements have been introduced in these curious branches of art; and specimens of pictures produced by these means have been given in the illustrated newspapers.

In the above article the reader will find an explanation of the scientific principles of electro-metallurgy, with a sufficient amount of detail to render the practice intelligible. More than this ought not to be expected in an encyclopædia article. Should more be desired, we cannot do better than refer to a volume just printed by order of the Commissioners of Patents, entitled 'Abridgments of Specifications relating to Electricity and Magnetism, their generation and applications.' This volume contains between 800 and 900 pages. Referring to those parts which relate to electro-coating, electro-deposition, &c., we have hundreds of patents, and as many applications, from the covering of a fish-hook to the metallising of a human corpse. There are also patents for coating steel pens and pen-holders, the hulls of ships and the ribs of umbrellas, for covering vitrified surfaces and for producing damascene inlaid or encrusted work, for making copper tubes and vessels, mirrors or specula, and artificial teeth and gums, for manufacturing the soles of boots and shoes, chairs, bedsteads, and coffins, daguerreotype plates and gold thread, hinges, mantel-pieces, mathematical instruments and projectiles, spoons and forks, wire gauze; for metallising fibrous materials, for all kinds of ornamentation, for protecting telegraph cables and sepulchral monuments, &c., &c.; to say nothing of printing, engraving, and the various other applications already described or referred to in our article.

ELECTRO'METER. This term strictly applies only to instruments adapted to measure electricity; it has however been applied in a more extended sense to those which only indicate the presence of that fluid; but these are more correctly denominated *electroscopes*.

Of the former kind is the *Balance of Torsion* invented by Coulomb, to which we have had occasion to refer in the articles ELASTICITY and ELECTRICITY. The following is a description of this delicate instrument.



A very fine metallic wire, or, which is better, a single thread of silk taken from the cocoon, or, which is better still, a filament of spun glass, is fixed at the upper extremity, and at the lower it supports horizontally a fine needle made of a good non-conducting substance, as gum-lac, to one of the ends of which is attached the body to be electrised, as for instance a small ball of elder-pith; at the top of the suspended string there is placed a plate moveable with friction on a glass cylinder, in which the thread is contained, by which any requisite torsion may be given to the thread, which is shown by an index on a micrometer screw; the body of the large cylinder which encloses the needle is also surmounted with a graduated brass circle. In electrical experiments the index of the micrometer is on its division zero, and the plate is turned round so as to bring the needle and pith-ball to the zero of the graduated circle on the string. Again a second ball is attached to the extremity of a fine isolating cylinder inserted in the apparatus so that both balls may be in contact without pressure. The balls are then electrised by communication with some isolated and electrised body, and acquiring similar electricities repulsion immediately takes place. That attached to the needle being moveable with it, carries it round through a certain angle, and after some oscillations settles at a definite position with respect to the fixed ball, this angle being indicated by the lower graduated arc; the elastic force of torsion is then in equilibrium with the moving force of repulsion between the balls, and hence a measure of the latter can be obtained. In such experiments only a very small electrical charge is communicated to the balls.

Coulomb, in seeking the law of electrical action, found that in the first instance of his experiment the needle deviated by 36°. Then, communicating a torsion to the thread in a direction tending to diminish this deviation, he found that the micrometer index traversed 126° to reduce the angle of deviation to 18°, and 567° degrees of torsion was necessary to bring it to 8½°; the thread being twisted by forces applied at both ends, it is evident that the entire torsions in the two latter cases are 126° + 18° = 144 and 567° + 8½° = 575½°, while in the first case it is only 36°. By comparing the deviations with the torsions, it was easily seen that the force of repulsion varied inversely as the square of the distance between the balls. It should be remembered in such experiments, that if the torsion of the thread be too great its elasticity will act imperfectly, and be no longer proportional to the angle of torsion. [ELASTICITY.]

In like manner the law of attraction of differently electrised balls was ascertained, the torsion being then employed in resisting the attraction. We may observe here that the results thus deduced are necessarily approximative, and not exact, because the neutral electricity of the balls being partly decomposed by the mutual influence of the electricities communicated, the small forces thus arising interfere with the actions which should be due to the latter only. The attractive and repulsive forces may also be estimated by disturbing the needle a little from its position of equilibrium, and observing the number of oscillations which it makes in a given time, as was adopted by Biot in determining the law of electro-magnetic action of a galvanic current.

The proof-plane also used by Coulomb was merely a small disc of gilt paper fastened to an isolating handle; this he employed to discover the distribution of electricity on the surfaces of bodies by touching them with the plane at various points, and observing by means of the torsion-balance the quantity of electricity taken up by contact, which he assumed to be proportional to the quantity of electricity at the point touched.

Various instruments have been constructed for estimating approximately the total quantity of electricity in the charge of an electrised body, such as Lane's, Henley's, and Cuthbertson's electrometers. Henley's quadrant electrometer is represented under ELECTRICITY. The most precise instruments of this description are those invented by Harris: a description will be found in his 'Rudimentary Electricity,' under the names of 'Quadrant Electrometer of Double Repulsion,' the 'Bifilar Balance,' the 'Hydrostatic Electrometer,' the 'Scale-beam Electrometer,' the last of which is represented under ELECTRICITY.

Electroscopes indicate the presence of very small quantities of electricity, and therefore are generally used with a condenser; as in the case of the gold-leaf electroscope, consisting of two small portions of gold-leaf laid flat together; and when made to communicate by a conducting stem, with a condenser which has acquired electricity from a very feeble source, they diverge from each other. They have been also employed to indicate atmospheric electricity. The gold-leaf electroscope is represented under ELECTRICITY.

Instruments have also been constructed for the purpose of indicating the existence of electrical currents, a description of which will be found under GALVANOMETER, THERMO-ELECTRICITY, RHEOSTAT, &c.

ELECTRO-MOTIVE MACHINES. The various rotatory motions produced by the electro-magnetic force, and the enormous attractive power developed by electro-magnets have led some ingenious mechanists at various times to seek in electricity a motive power which it was thought would rival even steam itself. A common method of constructing an electro-motive machine was to connect a set of armatures like the spokes of a wheel, so as to revolve horizontally round a point situated midway between the poles of a horse-shoe electro-magnet. In such case the opposite ends of each armature would be attracted by the pole nearest to it, and if the name of that pole were suddenly changed the same armature would be as suddenly repelled. In this way each spoke would be drawn under the poles of the electro-magnet, and immediately driven away with equal force, and the momentum caused by its approaching by attraction, would cause it to pass beyond the attracting pole, an effect which would be assisted by the substituted repulsion. In this way a rotatory motion of the wheel could easily be produced. Unfortunately for so promising a result, these rotations have no permanent momentum, and are incapable of overcoming resistance or doing any work. It is true that an enormous weight may be suspended from soft iron by a very small outlay of chemical force, but there is so rapid a diminution of the inductive force by distance, the magnetic attraction diminishing according to the law of the inverse square of the distance of the surface of the magnet and the armature, that however great the force required to separate the armature when actually in contact with the magnet, their tendency to approach each other when separated is so small that it seems hopeless to expect mechanical effect from this source. For it is only from the strong tendency in these bodies to approach each other that rotation can become a source of mechanical effect. There are also other objections arising from the action of induced electricity to be overcome in these machines.

In the Great Exhibition of 1851, a number of these machines, or their models, were exhibited, and the Jury Report, Class X, expresses rather too flattering an opinion as to their value, especially when it is said, "We cannot help flattering ourselves that the attainment of this mysterious motive force will soon be followed by making it available for practical purposes." About a year or two ago there was a stormy discussion in the 'Times' newspaper, as to the merits of these machines, conducted chiefly by the inventors themselves.

Professor Wheatstone, who generally hits upon the best method of bringing about a result, has contrived what we consider to be the best electro-motive machine. We shall perhaps be able to give a sufficient idea of it in a few words of description. Conceive a number of electro-magnets arranged in a circle with their poles alternating and directed towards its centre. The number of electro-magnets actually employed is eight, so that there are sixteen magnetic poles arranged in a circle. Within this circle is placed a cylinder of iron, not quite concentric therewith. A portion of the outer surface of this cylinder is in contact with the poles of one of the electro-magnets, and the cylinder is free to roll upon them, and to move as they attract it. It is worthy of remark that in this arrangement attraction is alone concerned, repulsion having been got rid of by making the inner cylinder of soft iron, and the objection that the electro-magnetic force rapidly diminishes with the distance is met by making the cylinder roll upon the poles. Now it is ingeniously contrived that as soon as the cylinder, obeying the attraction of one of the electro-magnets rolls upon its poles, it acts upon certain springs, whereby the electro-magnet which attracted the cylinder is unmade, and ceases to hold it, while the next electro-magnet is instantly made and attracts the cylinder, which rolls upon it, unmakes it, makes the next, and so on in quick succession throughout the circle. Connected with the centre of the cylinder, and the centre of the circle of magnets, is a crank which is thus set in motion, and by which it is proposed to impart motion to machinery, &c.

ELECTROPHORUS. An instrument invented by Volta for generating electricity by induction. It consists of a thick disc of resin 12 or 15 inches in diameter, called the *plate*, resting on tin-foil, or cast in a tin plate called the *sole*. The plate is furnished with a metal disc or *cover*, insulated by means of a glass handle. In producing electricity with this instrument the cover is removed by its glass handle, and the plate is excited by flapping it with dry fur or flannel. On putting the cover down upon it a spark of resinous electricity may be drawn from it, and on uninsulating it, and then raising it, it will give a still brighter spark of vitreous electricity. On putting the cover down again, another resinous spark may be obtained, and on touching it and then raising it another vitreous one, and so on for any number of times. In these operations the first action is to give to the resin a charge of negative electricity on its upper surface, while the under surface, being connected with the earth, becomes positive to an equal extent, the particles of the cake being polarised. [ELECTRICITY.] The cover being now placed upon the cake, and touching it only in a few points, it is scarcely acted on by conduction, but induction so operates as to throw the under surface of the cover into a positive state, while an equal amount of negative electricity is set free on its upper surface, and this passes off in the form of a spark on presenting the knuckle or other conductor. On raising the cover the + electricity which was retained on the lower surface by induction, is now in excess, and passes off in the form of a spark when a conductor is presented to it. In the mean time the plate which acts by induction has lost none of its charge, and is ready to act again by induction on placing down the cover. The cover must not, however, come into contact with the sole, or the whole of the charge may be drawn off from the plate.

The instrument derives its name from the circumstance of the cover *bearing off* repeated charges of electricity. The electrophorus in connection with the condenser [ELECTRICAL CONDENSER] has had considerable influence in enlarging our knowledge of the most important feature of all electrical inquiry, namely induction. The electrical plate as formed by Volta consisted of equal parts shell-lac, common resin, and Venice turpentine. Pfaff recommends eight parts colophon, one gum-lac, and one Venice turpentine; while Roberts prefers ten parts gum-lac, three of colophon, two white wax, two Venice turpentine, and half a part of pitch. The materials should be well incorporated by stirring up in a pipkin, aided by a gentle heat. Harris remarks that small plates of glass, sealing-wax, or brimstone are well adapted to serve as electrical plates.

ELECTRO-STATICS. [ELECTRICITY; ELECTRO-DYNAMICS.]

ELECTROSCOPE. [ELECTROMETER.]

ELECTROTYPE. [ELECTRO-METALLURGY.]

ELECTRUM, from the Greek *electron* (ἤλεκτρον). Pliny says this term denotes two substances, namely, amber and a metallic alloy composed of four parts of gold and one part of silver. "Ubicumque quinta argenti portio est *electrum* vocatur." ('Hist. Nat.,' lib. xxxiii, section 23; 'Hardouin,' tom. ii., p. 619.) The term electron, in the Odyssey of Homer, is supposed to mean amber.

The metallic electrum was in use in the Roman times: it is uncertain whether it was known to the Greeks. The Romans were partial to it for its brilliancy. Pliny, a few sentences lower down than the passage just quoted, says, "Electri natura est ad Lucernarum lumina clarius argento splendere." The Romans used it frequently for what we term plate.

Lampridius, in his Life of Alexander Severus, remarks, that this prince caused coins to be struck in honour of Alexander the Great, both of electrum and gold. "Alexandri habitu nummos plurimos figuravit: et quidem electreos aliquantos: sed plurimos tamen aureos." ('Hist. Aug. Scriptores,' p. 922.)

Isidorus, in his Origines (li. xvi., c. 23), speaks of three sorts of electrum: 1, amber; 2, a metal so called, found in a natural state; and 3, a metal compounded of three parts of gold and one of silver.

ELECTUARY, a term applied to a compound of various medicines, united by means of syrup, or wine, and formed into a soft mass, nearly of the consistence of honey. Substances in the state of powder or extract were thus combined, and rendered capable of being swallowed without their natural taste, which might be unpleasant, being perceived. Formerly electuaries consisted of a great variety of ingredients, often very unsuitable to be taken together. In the present day the few electuaries which are prescribed are much simpler in their composition. Many compounds which were formerly preserved in a soft state are now kept in a hard dry condition, and termed *confections*.

ELEENCEPHOL. A substance found in the brain of man, but now believed not to be a distinct chemical compound, but a mixture of oleine, oleophosphoric acid, cerebric acid, and cholesterin.

ELE'GIT, so called from the entry of its award upon the roll, "quod elegit sibi executionem" (because the plaintiff hath chosen the writ of execution), is a writ of execution first given by the statute Edw. I., cap. 18, but the operation of which has since been greatly extended. It is directed to the sheriff of the county where the defendant's property lies, and commands him to make delivery of the debtor's lands and all his goods (except oxen and beasts of the plough) to the plaintiff.

The sheriff, immediately upon the receipt of this writ, empanels a jury, who appraise the debtor's lands as well as his goods, and if the goods alone are insufficient to pay the debt, then the sheriff, upon the finding of the jury, delivers the lands over to the party suing out the writ, who thereupon becomes what in law is termed a *tenant by elegit*, and continues to occupy them until the whole of his debt and damages are satisfied. The tenant's interest in the land is only a chattel, and as such goes to his personal representatives.

Before the statute of Edward I. a judgment creditor could only have obtained satisfaction of his debtor's goods by the writ of *fieri facias*, and of the present profits of his lands by a *levari facias*; but as the latter writ did not extend to the possession of the lands themselves, a defendant might, if he thought proper, alien the property, and thus oust the plaintiff of his remedy. This has, with other defects, been remedied by the statute 1 & 2 Vict. c. 110.

When the judgment is satisfied out of the estate, the defendant may recover his lands either by an action of ejectment, or by a suit in equity. (*Blackst. Comm.* Mr. Kerr's ed., vol. iii. p. 457.)

ELEGY, from the Greek, *élegos* (ἔλεγος, whence ἐλεγεῖον), in English commonly means a short poem composed on some person's death; also, in a more general sense, any mournful or serious poem, as, for instance, Gray's 'Elegy in a Country Church-yard.' The Greek word, *élegos*, is properly a strain of lament; *elegeion*, the form of versification in which such strains were first composed by the Greeks, that is, the combination of an hexameter and a pentameter (commonly called long and short) verse; *elegeia*, a poem made up of such verses. (Müller, 'Hist. of Lit. of Greece.') The elegiac was the first variation from the hexametral, or epic, measure; and this change of form corresponded with a change of subject: the poet in epic composition keeping himself and the workings of his own mind out of sight; while on the contrary, the free and full expression of the poet's feelings, as affected by external circumstances, constituted the essence of the Greek elegy. Hence arises its variety; the elegies of Callinus and Tyrtæus (the earliest) being political and warlike; of Mimnermus, contèmplative and melancholy; of Theognis and Solon, moral and political, &c. It was at first more peculiarly appropriated to social meetings, and therefore equally fit for topics of political and local interest, and for those which refer to the common feelings of our nature, as love, regret for the perishableness of human things, exhortations to the enjoyment of the present hour, and the like. The elegiac was also a favourite measure for epigrams, that is, taking the word in its proper sense, inscriptions. [EPIGRAM.]

Catullus is the first Latin elegiac writer of any note; he was followed by Tibullus, Propertius, and Ovid, with many others of the Augustan age, whose poems are either totally lost, or have only come down to us in fragments. With them political and moral subjects find no place; the elegiac verses of Catullus (a small part of his poems) are, for the most part, either mournful or satirical; those of the other poets above named are chiefly devoted to love, fortunate and unfortunate. Ovid, however, has taken a wider scope of personal feelings in his Epistles from Pontus, and of historical and mythological learning in his Fasti.

ELEMENT. In chemistry this term is applied to such substances as cannot be resolved into two or more simpler kinds of matter. Thus by no analytical processes can anything different from themselves be separated from gold, silver, sulphur, or iron, and therefore these substances are termed elements, whilst potash, common salt, and lime are compounds, because they can be resolved respectively into potassium and oxygen, sodium and chlorine, and calcium and oxygen. Every substance which does not thus admit of analysis must be regarded as an element; in early periods in the history of chemistry many substances were classed as elements which have since been proved to be compounds, and it is not impossible that the progress of knowledge may enable us thus to resolve some of the elements of the present day, nevertheless the probability of such an occurrence is at present exceedingly remote. About sixty-two elementary forms of matter are now known; for a list of them, see ATOMIC THEORY.

ELEMI, a resin, of which there are two or more sorts, brought from different parts of the world, and apparently produced by different kinds of trees. The West Indian or American elemi is commonly referred to the *Amyris elemifera* (Linn.), but the very existence of such a species is doubtful, unless it be synonymous with the *Amyris Plumieri* (Dec.), of the Antilles, and the *Icica Icicariba* of Brazil. The East Indian elemi is obtained from the *Amyris zeylanica*, *Balsamodendron zeylanicum* of Kunth., *Terebinth* (Retz.), while a third sort, called African, or elemi verum, is referred to the *Eleagnus hortensis*. A substance resembling elemi, and capable of being applied to similar purposes, may be procured from several plants. West Indian elemi occurs in irregular-shaped small pieces, which run into masses, of a yellowish colour, of an agreeable odour, which is most perfectly developed by the application of heat. The consistence is at first soft, but it hardens with age, and even becomes brittle, losing some of its odour. Specific gravity 1·083. It seems to contain a principle termed elemine. Elemi is recommended as an ointment, but it is chiefly used to form pastilles, or to burn as incense.

A sealing-wax, into the composition of which elemi largely enters, if applied to cover the tops of the corks of wine bottles, is said to be an efficient preventive of the attacks of the small beetles (thought to be introduced into wine-cellars along with the sawdust sometimes used in packing the bottles), which, eating through the corks, cause the entire loss of the wine. Some believe the destruction of the corks to be caused by the action of the wine.

ELEMI-RESIN. A product obtained from the *Amyris elemifera* of the West Indies, and from the *Ceylanica* of the East Indies. Hess gives the formula $C_{10}H_{16}O$, whilst Rose assigns to it $C_{40}H_{33}O$. Elemi is, however, most probably a mixture. It is known to contain two resins, one soluble in cold alcohol and crystallisable, the other amorphous and containing a less proportion of carbon.

The specific gravity of elemi is 1·08. When distilled with water it yields a limpid, colourless, inflammable oil, which rotates the plane of polarisation to the left, boils between 330° and 345° Fahr., has a specific gravity of ·849, and possesses the same composition as oil of turpentine. With hydrochloric acid it forms an artificial camphor of the formula $C_{10}H_8HCl$.

ELENCHUS, the Latin form of the Greek *elenchos* (ἔλεγχος), and commonly translated by the words *argumentum, inquisitio, confutatio*, and *demonstratio*, is a term of frequent use in the Aristotelian system of logic, and signifies argument, replication, refutation, or the point, subject, or nature, of dispute or demonstration. (See the authorities cited in Valpy's edition of Stephens's Greek Thesaurus under Ἐλέγχω.) Aristotle defines *elenchos* as "a syllogism of contradiction," that is, an argument alleged in opposition to another; and Mr. Thomas Taylor, in his translation of the 'Organon,' considers the Greek term to be precisely equivalent to *redargutio* in Latin. By some of the early English authors the noun *elench* is used in a similar sense, and also the verb *elenchize*, meaning to argue with captious or sophistical opposition. (Johnson's 'Dict.') In the two last books of the 'Organon,' entitled Περὶ τῶν Σοφιστικῶν Ἐλέγχων, Aristotle minutely classifies and discusses the various kinds of sophistical elenchi, or modes of argument, used by contentious sophists. The sophism which, in scholastic phraseology, is designated *ignoratio elenchi*, that is, a real ignorance of, a mistaking, or sinister deviation from, the argument, or question under discussion, consists in proving something irrelevant, and which, as it may be true without affecting the truth of the real proposition, with which it has no necessary connection, does not determine, though it may seem to determine, the question. Aristotle includes under this designation the introduction of anything extraneous to the point in dispute (ἔξω τοῦ πράγματος); the disproving of what is not asserted, as well as the proving of what is not denied. Examples of this species of sophism are of very frequent occurrence in discourses which display the rhetorical artifice of appealing to passions and prejudices, and resort to injurious imputations, or ludicrous and satirical illustration; especially in religious, political, and forensic disputations, which affect individual interests and feelings, and in which the predominant desire is not the exhibition of truth, but merely the obtaining of victory; for a disingenuous disputant when excited, and conscious of the superiority of his adversary's argument, strives to elude conviction by the stratagem of *deploying*, and seeks to gain a sinister advantage and triumph, by proving or disproving, not the real proposition in question, but one or more which in some way are apparently involved or implied, so as to create the assumption of identity. The following instance is given by Dr. Kirwan ('Essay on Logic,' vol. ii. p. 440): "Paschal arguing against atheism insists that it is *more dangerous* than theism, whereas the point in debate is the *truth*, and not the *prudence* of either system. Some Christian sects use similar arguments." Mistake or misrepresentation of the question to be determined, and the consequent proving of what is not to the purpose, are also common in didactic and conversational discussions, and the sophisms of *petitio principii* and *non causa pro causa* are frequently combined with the *ignoratio elenchi*. In all cases of irrelevant conclusion, when something is proved which does not in reality contradict the adversary's proposition, the latent fallacy is best exposed by showing that both propositions may be equally true (Archbishop Whately's 'Logic'); and the best means of preventing sophistical deception of this nature is to keep the attention constantly fixed upon the precise point of dispute, neither wandering ourselves, nor suffering our opponent to wander or make any substitution. (Dr. Watts's 'Logic.') In dramatical writing the *ignoratio elenchi*, or as it is otherwise called, the *quid pro quo*, is frequently adopted as a very effective expedient for the production of laughter. Numerous and long continued instances of consistent dialogue, displaying the most ingenious and amusing *équivoque* or cross purposes, are to be found in the comedies of Molière, the source of amusement being in each party's "ignorance of the question" about which the other is concerned.

ELEPHANTI'ASIS (ἐλέφας and ἐλεφαντίασις), *elephant* and *elephant disease*, so called partly on account of some supposed resemblance of the diseased skin to that of the elephant, but principally from the formidable nature of the malady. It is disgusting to the sight, says Aretæus, and in all respects terrible, like the beast of similar name.

The term is now commonly applied to two different diseases; first, to a peculiar disease of the skin, one of the most formidable of the dreadful cutaneous affections which occur in hot climates, and more particularly where agriculture and the arts of civilisation are imperfectly advanced; and secondly, to a peculiar disease of the leg, which becoming enormously tumid, is conceived to bear some resemblance to the leg of an elephant.

The first distemper, elephantiasis properly so called, is a tubercular disease of the skin. The tubercles present a shining appearance; they are of different sizes, and are of a dusky red or livid colour on the face, ears, and extremities. The tubercles are accompanied with a thickened and rugous state of the skin, a diminution or total loss of its sensibility, and a falling off of all the hair excepting that of the scalp.

The disease is wholly unknown in this country. It is described as slow in its progress, sometimes continuing several years without materially deranging the functions, but gradually producing an extraordinary degree of deformity. The following is the description commonly given of this formidable malady; but there is reason to believe that the picture is much exaggerated.

The alæ of the nose become swelled and scabrous; the nostrils are dilated; the lips are tumid; the external ears, particularly the lobes, are enlarged and thickened, and beset with tubercles; the skin of the forehead and cheeks grows thick and tumid, and forms large and prominent rugæ, especially over the eyes; the hair of the eye-brows, the beard, the pubes, axillæ, &c., falls off; the voice becomes hoarse and obscure; and the sensibility of the parts affected is obtuse or totally abolished, so that pinching or puncturing them gives no uneasiness. This disfiguration of the countenance suggested the idea of the features of a satyr or a wild beast; whence the disease was by some called *Satyriasis*, and partly also on account of the excessive libidinous disposition said to be connected with it; and by others *Leontiasis*, from the laxity and wrinkles of the skin of the forehead, which resembles the prominent and flexible front of the lion.

As the malady proceeds, the tubercles begin to crack, and at length to ulcerate; ulcerations also appear in the throat and in the nose, which sometimes destroy the palate and the cartilaginous septum; the nose falls; and the breath is intolerably offensive; the thickened and tuberculated skin of the extremities becomes divided by fissures, and ulcerates, or is corroded under dry sordid scabs, so that the fingers and toes gangrene and separate joint after joint.

The large misshapen leg, which is also often termed elephantiasis, arises from a repeated effusion and collection of a lymphatic and gelatinous matter in the cellular membrane under the skin, in consequence of inflammation of the lymphatic glands and vessels. The skin itself is much thickened in the protracted stages of the disease, and its vessels become greatly enlarged; its surface grows dark, rough, and sometimes scaly. As the effusion first takes place after a febrile paroxysm, in which the inguinal glands of the side about to be affected are inflamed, and the limb is subsequently augmented in bulk by a repetition of those attacks, Dr. Hendy termed the malady the glandular disease of Barbadoes, in which island it is endemical. In England it is often called the Barbadoes leg. Except when these paroxysms occur, the functions and constitution of the patient are not mainly injured, and they often live many years, incommoded only by carrying about "such a troublesome load of leg."

In this country the disease is only seen in its inveterate stage, after repeated attacks of the fever and effusion have completely altered the organisation of the integuments of the limb, and rendered it altogether incurable. In this state the swelling is hard and firm, does not pit on pressure, and is entirely free from pain. The skin is thickened and much hardened; its blood-vessels are enlarged, particularly the external veins, and the lymphatics distended; and the cellular substance is flaccid and sometimes thickened, and its cells much loaded with a gelatinous fluid. The muscles, tendons, ligaments, and bones, are generally in a sound state.

In this advanced stage the disease is altogether irremediable. Little success indeed seems to have attended the practice employed in the earlier stages, which has chiefly been directed to alleviate the febrile paroxysms by laxatives and diaphoretics, and subsequently to strengthen the system by cinchona. Local bleeding has not been employed; but after the fever and inflammation have subsided, the practice of binding the limb in a strong bandage is strongly recommended as the best means of exciting absorption, and of reducing the swelling. (Dr. Bateman's 'Practical Synopsis of Cutaneous Diseases.')

ELEVATION, ANGLE OF. [ALTITUDE.]

ELEVATION IN ARCHITECTURE. [DESIGN, ARCHITECTURAL.]

ELEUSI'NIA, the great mystic festival of Demeter [DEMETER] celebrated at Athens and Eleusis in the month Böedromion (September): the most important and solemn religious festival of Greece. The lesser mysteries were celebrated in the month of Elaphebolion (March) at Agræ, on the Ilissus, and were a sort of preparation for the Eleusinia.

The great festival began on the 15th Böedromion, and lasted nine days both at Athens and Eleusis. The first day was called the assembling (*ἀγυρμός*): on it all who had been initiated in Elaphebolion were assembled at Athens and invited to complete their sacred duty. The second day was named *ἅλαδε μύσται*, "to the sea ye initiated!" from the words of the proclamation, by which they were admonished to purify themselves. This purification took place in the *ῥειτοί*, two streamlets of salt water running into the gulf of Salamis, and which separated the territory of Eleusis from the rest of Attica. The third day was called *εἰς λέχη μύσται*, from some ceremonies imitative of the marriage of Persephone, which took place on that day. On the fourth day there was a procession, in which a vessel filled with poppy heads and pomegranates, emblems of fertility, was placed on a waggon drawn by oxen, and followed by women bearing other mystic emblems. The fifth was called the "day of the torches," *λαμπάδων ἡμέρα*, on account of a lampadephoria, or torch-procession, in which the initiated, clad in purple robes and crowned with myrtle, marched two and two round the temple, followed by the worshippers bearing torches, symbolising, as is supposed, the wanderings of Demeter in search of Persephone. The initiation took place on the sixth and seventh days of the feast. The sixth day, which was called Iacchos, was the chief day of the Eleusinia. On this day the statue of Iacchos was carried in procession from the Cerameicus to Eleusis, attended by vast crowds of shouting followers. It was during the night succeeding this day that the worshippers were initiated into the inner mysteries. On the following day, which was named the return of the fully-initiated (*νοστοῦσιν οἱ ἐπόπται*), the statue of Iacchos was carried back again, and the initiated returned in procession to Athens, exhibiting the most tumultuous revelry. The eighth day was called Epidauria, in honour of Æsculapius, who did not arrive from Epidaurus to be initiated until after the return of the Epoptæ, and it was observed as a sort of supplemental day of initiation. The ninth day was called *πλημοχόη*. The ceremony of this day consisted in the symbolical overturning of two vessels filled with wine and water, the ceremony being accompanied with certain mystic rites.

The persons initiated at the lesser mysteries were called *μύσται*, from *μυῶ* "to close up," because they were bound to strict silence; those who had passed through the Eleusinian ceremonies were called *ἐπόπται* or *ἔφοροι*, "contemplators," because they had been admitted to see the sacred objects; they were also hailed as happy and fortunate (*εὐδαίμονες*, *ὄλβιοι*).

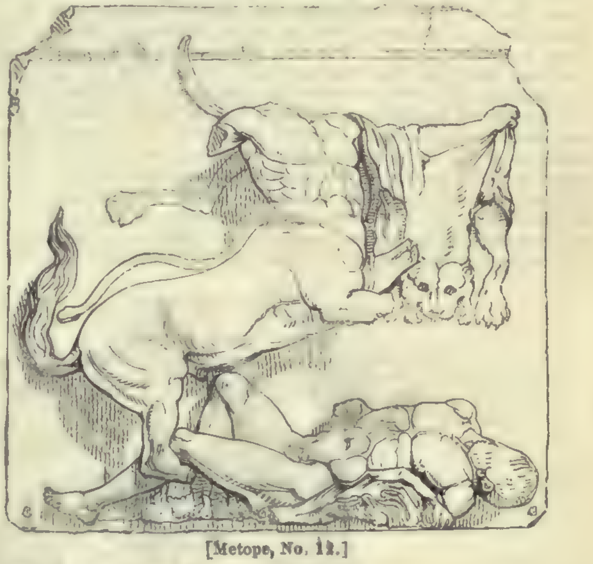
Of the nature of the initiation nothing is certainly known. It is probable that some notions were imparted of a future state of existence. But even this, though stated by early writers, is by no means clear; and there seems to be little ground for supposing with Warburton (Div. Leg. of Moses, b. ii. § iv.) that the ultimate secret was the unity of the Godhead. It may however, from the general tenor of the various references, be inferred that the secrets were of an elevating rather than a debasing character, and that their tendency was to raise the conception of the nature of human life, its purpose, and its duties. Every Athenian was obliged to pass through these ceremonies once in the course of his life. Bastards, slaves, and prostitutes, as well as strangers, and in later times Christians and Epicureans, were excluded from the Eleusinia. To reveal any of the mysteries, or to apply to private purposes any of the hallowed solemnities, was considered a capital crime. The priests at Eleusis belonged to the house of the Eumolpidæ. The chief priest was called the Hierophant, the second in rank the Torch-bearer (*δᾳδοῦχος*); the third the Sacred Herald (*ἱεροκήρυξ*), and the fourth the Altar-priest (*ὁ ἐπὶ βωμῷ*).

ELGIN MARBLES, the designation given to a collection of ancient sculpture, chiefly from the Acropolis of Athens, whence it was obtained by the Earl of Elgin (who had been the English ambassador to Turkey) between the years 1801 and 1812. This collection was purchased in pursuance of an act of the legislature, dated July 1st, 1816, for the sum of 35,000*l.*, and is now deposited in the British Museum, in what are designated the First and Second Elgin Rooms.

The Parthenon, or Temple of Pallas Athene at Athens, whence the more important of these sculptures were obtained, was built during the administration of Pericles, about the year B.C. 448. It was constructed entirely of white marble from Mount Pentelicus; Callicrates and Ictinus were its architects; and its sculptures were produced partly by the hand and partly under the direction of Phidias.

The sculptures of the Parthenon in the Elgin collection are of three descriptions: Metopes; a portion of the Frieze of the cella; and Statues and their parts from the tympana or pediments.

The *Metopes* are fifteen in number, from the frieze of the peristyle on the southern side of the building, and bear reference to the contest between the Centaurs and the Lapithæ. [CENTAURS.*] There is a sixteenth Metope, placed as No. 9; but it is a cast from one now in the Museum of the Louvre at Paris, the original of which, formerly belonging to the same series, was purchased (for 25,000 francs) for that collection in 1818, at the sale of the Count de Choiseul Gouffier, who before the French Revolution had been his king's ambassador in Turkey. The Metopes are executed in high relief, and are the finest examples of that style in existence. The admirable art displayed in their design and execution, and their exquisite adaptation to the position they originally occupied, have been pointed out in the article ALTO-RILIEVO, col. 252, et seq., where an engraving is given of one of them (No. 2). We add here an engraving of No. 12, which is especially admirable for the accurate expression of the dying Greek.



[Metope, No. 12.]

The most interesting of the Metopes are Nos. 3, 11, 12, and 13. The three last mentioned are the finest in point of execution.

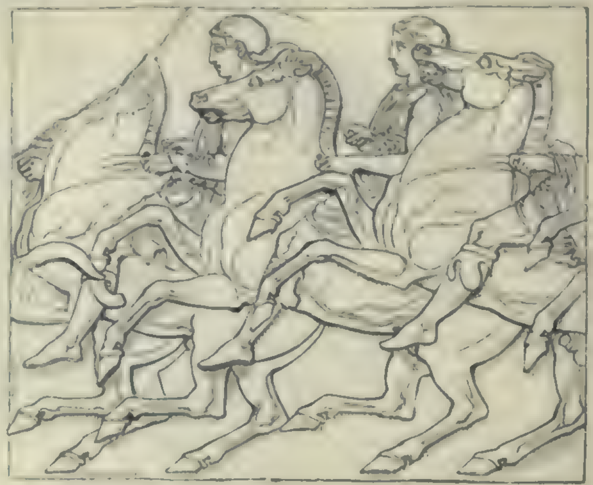
In an uninterrupted series of very low relief, placed round the cella, immediately below the ceiling of the porticoes of the Parthenon, was the *Frieze*, representing the solemn quinquennial procession, called the Panathenæa. The procession was represented as advancing in two parallel columns from west to east, one along the northern, the other along the southern side of the temple, and facing inwards after turning the two angles of the eastern front, and meeting towards its centre. Such was the frieze in its original position, when it formed an uninterrupted series of sculptured slabs, 524 feet in extent and 3 feet 4 inches high: the base of the slabs was 40 feet from the floor of the platform. Of its remains the Elgin collection possesses an extent, in slabs and fragments of marble, beginning at No. 17, of rather more than 249 feet, with a continuation of plaster casts of more than 76 feet. The greater part of the last are from portions of the sculpture which were not brought away, including a single slab, No. 23, which likewise belonged to the Count de Choiseul, now in the Museum of the Louvre; all forming a total of representation from the frieze of very near 326 feet. The bas-reliefs which at present compose the frieze in the Elgin Room, as far as they extend, are placed in the same order in which they were originally seen upon the Parthenon. Those on the principal front of the temple, namely, the east, are placed first, then follow those of the north, and lastly those of the west and south. They are arranged, in short, in the same manner in which the spectator viewed them as he approached the temple by the east, and walked round it by the north, west, and south. But the spectator in the Elgin Room has to keep in mind that what formerly surrounded an exterior wall now lines the interior of a room. For some remarks on their artistic character, see the article ALTO-RILIEVO, already referred to.

---

* The two representations of Centaurs and Lapithæ fighting, given under CENTAURS, should have been described as Metopes from the *Theseum*, not the *Parthenon*.

The slabs 17 to 24, form the eastern frieze, the portion which occupied the east end of the temple. The figures on slab 17, the Virgins of Attica, head the procession from the southern frieze. The slab 19, the longest in the collection, stood immediately above the eastern entrance or door, and was the centre of the composition. In this slab, upon the left, a Priestess is represented, supposed to be the wife of the principal archon, or chief magistrate of Athens, in the act of receiving from two canephori, or bearers of the mystic baskets, the articles serving for the rites of sacrifice. To her left stands the Archon, in a drapery which reaches from the head to the feet, receiving from the hands of a youth a piece of cloth folded in a square form in numerous thicknesses, conjectured to be the peplus, or embroidered veil, the sail of the Panathenaic ship, and the principal ornament of the procession. On each side of the groups which represent the priestess and archon are various seated figures, among which Zeus, Pallas Athene, Triptolemus, Æsculapius, and Hygeia are the most conspicuous. Another train of females head the procession as it comes from the northern frieze; and here the sculptures which adorned the eastern front of the Parthenon terminate. This part of the frieze is greatly mutilated; but the explanation of it is aided by some drawings of the Parthenon made in 1674, by Jacques Carrey for the Marquis de Nointel, at a time when the sculptures were a little more perfect. These drawings are in the Imperial Library at Paris, and copies of them are in the British Museum.

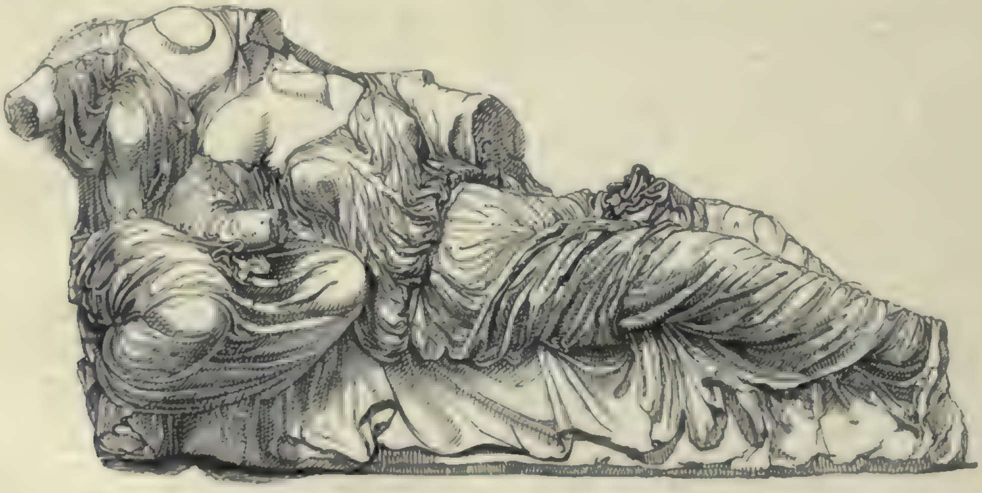
From the Nointel drawings it appears that the virgins who led the procession from the northern frieze, like those on the southern side, were followed by oxen led as victims; the foreigners settled in Athens were likewise represented, with the players on the flute and lyre; and a troop of citizens closed the train of persons on foot. But all these have disappeared. Nineteen slabs and a large portion of the northern frieze fell when the Acropolis was besieged by the Venetians in 1687, and these subjects were amongst them. The slabs with which the remains of this frieze now open, Nos. 25 to 31, consist of chariots and charioteers in action, followed by a train of horsemen, Athenian citizens of the second class, who served in the cavalry. This, the most beautiful portion of the whole frieze, extends from No. 32 to 46; in the forms and actions of the horses, in the attitudes and costumes of the riders, and in the distribution of the figures, the sculptors seem to have reached the highest excellence of their art in the department of low relief. (See cuts of No. 45, under ALTO-RILIEVO, col. 257, and No. 39 below.) The bridles of the horses, in many of the slabs here referred to, were originally of gilded bronze, as appears by the holes left in the marble. Small pieces of the bronze itself were found by Lord Elgin's formatori when taking moulds for him from this part of the frieze in its original position.



[Slab, No. 39.]

A single slab (but of exquisite beauty, No. 47, see cut of the principal figure, ALTO-RILIEVO, col. 255), is all which the Museum possesses in marble, of the western frieze. Plaster casts of fourteen slabs, which form the remainder of the western frieze, and which are still attached to the Temple, follow it, numbered 48 to 61. The western frieze extended over the front, and over the antæ of the opisthodomos, or back chamber. The direction of the figures is the same as that on the north side, namely from right to left. There is a peculiarity, too, in the frieze of the west end, which distinguishes it from that on the north and south sides of the temple. The subjects represented on the slabs of those two sides run one into another; that is, what was left imperfect in one slab is completed in the next; whereas in the west end the subjects are nearly complete on each piece of marble. The western frieze is likewise distinguished from those of the two sides of the temple by the comparatively few figures introduced into it.

We now come to that portion of the frieze which enriched the southern side of the Temple. The direction of the figures which form it is from left to right, and the numbers being in continuity from the western frieze, begin with the end of the procession, and extend from 62 to 90, round to the door of entrance into the Elgin Room: these slabs have been greatly injured. In this, as in the western frieze, the spectator is supposed to have his face turned respectively to the north and south sides of the temple. A considerable number of the slabs, Nos. 62 to 77, represent horsemen; 78 to 82 consist of chariots; a collection of citizens and old men, corresponding with those of the northern frieze, but more numerous, preceded these; all, however, but a single fragment of four women (No. 83) have disappeared. In the slabs and fragments numbered 84 to 90 we see the sacrificial oxen, and upon the turn of the slab 90 is a figure, believed to be that of a magistrate looking round upon the procession which follows him. He is interposed between the end of the procession on the northern, and the beginning of that upon the eastern frieze. At the end of the room are a few casts of isolated slabs which still remain at Athens.



[The Fates.]

Of the *Statues* and fragments from the tympana, or pediments, of the Parthenon, those toward the southern end of the Elgin Room, Nos. 91 to 98, are from the eastern pediment, the allegory of which represented the Birth of Athene; these consist of the neck, the shoulders, and the arms of the figure of Hyperion rising from the sea, the Horses of Hyperion, the magnificent recumbent statue called Theseus, the goddesses, supposed to be Demeter and Persephone, Iris with her veil inflated, Victory winged, the Fates, and the head of one of the Horses of Night. Those toward the northern end, Nos. 99 to 106, are from the western pediment, the allegory of which represented the Contest of Pallas Athene and Poseidon for the guardianship of Attica. With the exception of the first figure, the Ilissus, or River God, which is one of the finest Greek statues remaining, they are mere fragments, and were broken in an effort to remove them from the pediment after the siege of 1687. The greater part were recovered by Lord Elgin by excavating below a house which had been built out of the ruins beneath the pediment, and which he had purchased. They consist of the torso of Cecrops, a fragment of the face and the chest of Athene, the upper part of the torso of Poseidon, a fragment of the Ericthonian Serpent, the torso of Wingless Victory, and the lower part, or rather lap, of Leto.

[One of the Horses of Night.]

Between, and separating the sculptures of the two pediments (No. 119), stands an imperfect statue of a youth of the size of life, of exquisite workmanship, supposed to have formed part of a group of Dædalus and Icarus; all that is certainly known of it is, that it came in fragments, and from the Acropolis.

Casts from the temple of Theseus, and others from the bas-reliefs of the choragic monument of Lysicrates, are let into the eastern wall of the Elgin Room, the first above; the latter at the northern end, below the Panathenaic frieze.

Of the remainder of the Elgin collection, it may be sufficient to name a few marbles of highest character, such as the colossal statue of Dionysus, from the choragic monument of Thrasyllus, No. 111, and the Caryatide, from the Temple of Pandrosus, No. 128, engraved under CARYATIDES, col. 639. Of architectural fragments, the pieces of frieze from the treasury of Atreus, at Mycenæ, Nos. 177, 180, are the most ancient; the capital and portion of a shaft, No. 112, give a notion of the magnitude of the columns of the Parthenon; and the capital and shaft from the temple of Erectheus, No. 126, present the most beautiful example of the Ionic order now known. The fragment of the frieze of the temple of Erectheus is also one of the most valuable parts of the collection. Among the inscriptions, the Sigean, written in the most ancient Greek characters, and in the Boustrophedon manner, No. 107, claims the first place, followed by numerous others relating to the temples and buildings of Athens, some containing decrees or treaties, and a few inventories of the treasurers of the Parthenon: sepulchral inscriptions, urns, and stelæ abound in the collection; and among these the epitaph on the warriors who fell at Potidæa. (Thucyd. i. 63.) Votive bas-reliefs and offerings are also preserved in it in large number. The last article we shall name is a vessel of beautiful form, an urn of bronze; it was found in a tumulus situated on the road which leads from the Piræus to the Salaminian ferry and Eleusis, enclosed within the marble vase in which it now stands, and in it was a deposit of burnt bones, a lachrymatory of alabaster, and a sprig of myrtle in gold. It is supposed, from the last article, to have contained the ashes of some amatory poet.

[Ilissus.]

The possession of the Elgin collection has established a national school of sculpture in our country, founded on the noblest models which human art has ever produced. A tribute of gratitude is due to the memory of the nobleman to whose exertions the nation is indebted for it. If Lord Elgin had not removed them, the greater part would long since have been totally destroyed. In the last siege of Athens the Parthenon suffered additional damage.

ELIMINATION. This word is from *eliminare*, to drive out of doors, and it is used in mathematics to signify the formation of an equation or equations which do not contain a certain quantity, by means of given equations which do contain that quantity.

The simplest case of elimination, and therefore the best adapted for the explanation of the term, is the following: if A be equal to B and B be equal to C, than A is equal to C. In the result, B is eliminated. Any operation of algebra may produce elimination. We give four instances in which such a result is obtained by addition, subtraction, multiplication, and division.

1. $x+y=12$, $x-y=8$; add, $2\,x=20$: y is eliminated.
2. $x+z=a$, $y+z=b$; subtract, $x-y=a-b$; z is eliminated.
3. $xy=a$, $\frac{2x}{3y}=b$; multiply, $\frac{2}{3}x^2=ab$: y is eliminated.
4. $xy=a$, $yz=b$; divide, $\frac{x}{z}=\frac{a}{b}$: y is eliminated.

The process of elimination, in the case of more complicated equations, becomes difficult and frequently impracticable. So much is this subject connected with the theory of equations, that a treatise on the first would be the largest portion of one on the second. The writings on this subject are scattered, but most works on algebra contain all that is absolutely necessary.

Elimination is an essential part of very many mathematical processes: and in the present article, we can only attempt to give a few general notions, such as may help a student to connect different portions of his algebraical reading.

If the solution of equations were perfect, so also would be elimination. Having 10 independent equations for instance, each containing x, y, and z, if we could choose any three, and from these three find x, y, and z, we might substitute these values in the remaining seven equations, and thus form seven equations independent of x, y, and z. The general rule is that from m equations can be formed $m-n$ equations with n quantities eliminated. But not only must the equations be independent of each other, but no two or more must be capable of what we call simultaneous elimination. Suppose, for instance, x and y never enter into a set of equations except in functions of, say, x^2+y^2. If then we make $x^2+y^2=p$ and substitute, we have a set of equations not containing either x or y, but containing p. If by means of one of these we eliminate p from the rest, the process which does this, applied to the original equations, would allow of our eliminating both x and y by one equation only.

As to equations which are not purely algebraical, or which contain more than powers or roots, or combinations of them, we cannot pretend to say that there is any organised method of elimination existing, except that of solution. For example, we can eliminate x between the equations $x = \log(x+y)$, and $\sin(x+y)=e^y+x$, because it so happens that we can find y from the first, as in $y=e^x-x$; and this value of y may be substituted in the second. But if the first equation had been $x+2y=\log(x+y)$, we could not have found either quantity in *finite* terms of the other, from either equation. In such a case, we must have recourse to infinite series; with these instruments, elimination is always theoretically possible. But whether the results produced will be convergent, and otherwise convenient for use, must depend upon the circumstances of each case. When, however, elimination is spoken of, elimination in finite terms is generally understood.

Let us now take simple algebraical equations, and suppose a pair of them, containing x and y, as $xy^2-x^2y-2=0$, $y^3+x^3y-6=0$. Let these be $P=0$, $Q=0$, and proceed as in finding the most complicated common divisor of P and Q. And first, let it appear that there is a common divisor R, and let $P=RA$, $Q=RB$; so that A and B have not any common algebraical divisor. These equations may then be both satisfied by making $R=0$, which being only one equation between x and y, admits of an infinite number of solutions. But they may also be satisfied by $A=0$, $B=0$, the method of treating which falls under the next case.

Secondly, let there be no algebraical common divisor. Then, if we take y as the principal letter, there will at last be a remainder which is a function of x only: let this be X. Now it is easily proved that when P and Q vanish, X must vanish also: that is, no values of y can make both P and Q vanish, except in combination with values of x which make X vanish. All the required values of x, then, satisfy $X=0$. But is the converse true, and are all the roots of $X=0$ capable of combination with values of y, so as to satisfy both equations? This question will require some consideration.

In the preceding process, when y is made the principal letter, we have generally this alternative, either to introduce fractional functions of x into the result, or else to employ multipliers beforehand to avoid it: these multipliers will be functions of x. Let us allow of fractional functions of x, and suppose the process to be as follows:—

$$\begin{array}{l} P)\,Q\,(M_1 \\ \quad N_1)\,P\,(M_2 \\ \qquad\quad N_2)\,N_1\,(M_3 \\ \qquad\qquad\quad X \end{array}$$

We have then—

$$Q = M_1P + N_1$$
$$P = M_2N_1 + N_2$$
$$N_1 = M_3N_2 + X$$

Take a value of x which makes X vanish, and with this value of x, find a value of y which makes P vanish. We have then $Q=N_1=M_3N_2=-M_3M_2N_1$, or $N_1(1+M_2M_3)=0$. If then $1+M_2M_3$ should not happen to vanish, we must have $N_1=0$, or $Q=0$; that is, a root of $X=0$, combined with a value of y which makes $P=0$, also makes $Q=0$. But if it should happen that $1+M_2M_3=0$ is satisfied by the values of x and y, we have not this assurance that $Q=0$. Again, if M_1, M_2, or M_3, be made infinite by the value of x, the whole process fails. All we can say then is, that though $X=0$ must contain among its roots all the values of x required, it may possibly contain other values.

Next, suppose we introduce a multiplier to avoid fractions. Let it be convenient to begin with QZ and P, instead of Q and P. Then when QZ and P both vanish, X vanishes; but we can now only say that the roots of $X=0$ may, with proper values of y, satisfy one or the other of the systems $Q=0$, $P=0$, or $Z=0$, $P=0$. But if we take values of x which make $N_2=0$, $X=0$, it is easily seen that we satisfy both $P=0$ and $Q=0$, if no one of the quotients become infinite.

We shall take the following example, to show how comparatively complicated the results of a very simple instance may be. Let the equations be

$$P=xy^2-x^2y-2=0,\ Q=y^3+x^3y-6=0$$

Multiply Q by x, to prepare for division without fractions, and divide by P: the remainder is $x^2(x^2+1)\,y-(6x-2)$. Multiply P by $x^2(x^2+1)^2$ for a similar reason, and divide by the remainder. The second remainder, X, is—

$$2x^7+6x^6+2x^5+6x^4-36x^2+24x-4$$

One of the roots of this is $x=1$, with which it will be found that $y=2$ satisfies the equations $P=0$, $Q=0$. And in this instance it does happen that all the seven roots of X are capable, each with its proper values of y, of satisfying the given pair of equations.

If we take the principal letter to be x, the problem of ordinary algebraical elimination is reduced to eliminating x from two such equations as $ax^m+bx^{m-1}\ldots=0$, and $px_m+qx^{m-1}+\ldots=0$, where a, p, &c., are functions of the other letters. The mode which we have always adopted as most convenient in practice is as follows:—Suppose the equations to be

$$ax^3+bx^2+cx+e=0$$
$$px^3+qx^2+rx+s=0$$

Multiply by p and a, and subtract, which gives an equation of the form

$$Ax^2+Bx+C=0$$

Multiply by s and e, subtract, and divide by x, which gives another equation of the form—

$$Px^2+Qx+R=0$$

Repeat the same sort of process, making the first terms destroy each other, and then the last; we are thus led to two equations of the first degree, from which x may be at once eliminated. The same method will do when the equations are of different degrees, but in that case it is more convenient to bring down the higher to the lower, first, in the following manner:—Suppose the equations to be $ax^7+bx^6+cx^5+ex^4+\ldots=0$, and $px^4+qx^3+\ldots=0$. Multiply by p and by ax^3, and subtract, which gives a new equation of the form $Ax^6+Bx^5+\ldots=0$. Multiply by p and by Ax^2 (using the lower of the given equations), and subtract; and continue this process until a second equation of the fourth degree is found: after which proceed with the first and last terms as before.

The problem may be reduced to that of elimination between purely linear equations, as follows: Suppose it required to eliminate x between $ax^2+bx+c=0$, and $px^3+qx^2+rx+s=0$. Multiply both these equations by x, and we have then four equations involving the first four powers of x. Multiply again by x, which gives six equations involving the first five powers of x. Let these five powers be considered as five distinct quantities, x_1, x_2, x_3, &c., and eliminate these five quantities between the six linear equations, which are

$$\begin{array}{ll} ax_2+bx_1+c=0 & px_3+qx_2+rx_1+s=0 \\ ax_3+bx_2+cx_1=0 & px_4+qx_3+rx_2+sx_1=0 \\ ax_4+bx_3+cx_2=0 & px_5+qx_4+rx_3+sx_2=0 \end{array}$$

Since two equations are introduced at each new step and only one new power, there must be a step at which the number of equations becomes equal to the number of powers, after which, at the next step, the number of equations will be in excess by one, which is what is wanted for elimination. It is also worth notice that if we were to stop at the step at which the number of equations is the same as that of powers and find the powers as independent quantities, we might then eliminate between the first and second power, and produce the result in the form $A^2-B=0$.

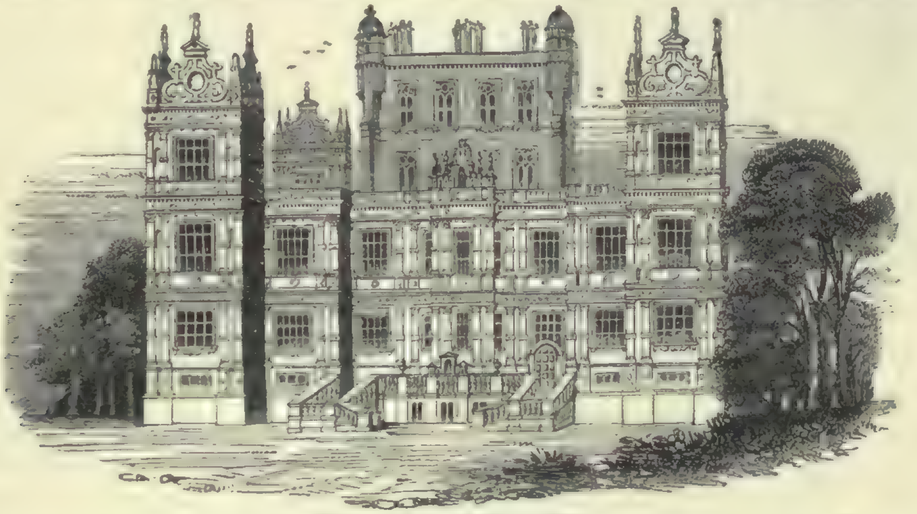
The following method, troublesome enough in actual operation, is the theoretical conquest of the difficulty. Let $\phi(x, y)=0$, $\psi(x, y)=0$, be two algebraical equations; and let the values of y from the first be X_1, X_2, X_3, &c. The equation which indicates that the second equation is satisfied by some root of the first is $\psi(x, X_1)\,.\,\psi(x, X_2)\ldots\ldots=0$; and the first side, being a symmetrical function of X_1, X_2, &c., can be expressed in terms of the coefficients of powers of y in $\phi(x, y)=0$, without actual solution. Let this be done, and we have that equation involving x only which is the necessary consequence of the two given equations.

On this subject see Dr. Peacock's 'Algebra,' vol. ii. cap. 44; or Mr. Sylvester's remarkable papers, 'Phil. Mag.' Dec. 1839, Feb. 1840, June 1841; also 'Cambridge Mathematical Journal,' vol. ii. pp. 232, 276, vol. iii. p. 183, vol. iv. p. 9.

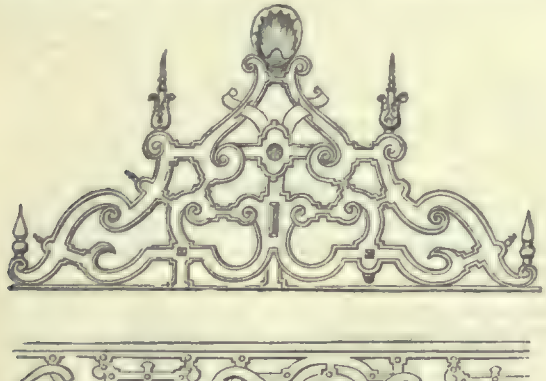
ELIXIR OF VITRIOL. [SULPHURIC ACID.]

ELIZABETHAN ARCHITECTURE. By this name is commonly distinguished that transition style which prevailed in England from about the middle of the 16th to the end of the first quarter of the 17th century, and was accordingly in its meridian during the long reign of Elizabeth. If it were worth while to disturb a name already fixed, it might with perhaps greater propriety be termed the *English Renaissance*, it being a style formed out of the Continental Renaissance engrafted upon our own Tudor and Old English domestic styles; and it was applied exclusively to secular and chiefly to domestic buildings, in which respect it was very differently circumstanced from the Gothic styles, which were almost as exclusively ecclesiastical in character and purpose. The age of Elizabethan architecture was that of palace-building, not church-building; and a style developed itself which was eminently palatial in many of its qualities,—certainly not deficient in stateliness (one very important ingredient),—nor more deficient in picturesqueness.

It is unjust to speak of Elizabethan architecture, as is sometimes done, as being marked by the introduction of the Grecian orders, those employed in it having nothing whatever in common with the orders of antiquity but that sort of resemblance which renders us all the more sensitive of the prodigious difference between the respective styles. Considered as classical or antique, they can be regarded only as grotesque parodies, since the application of them in all the varieties of the Renaissance style is as contrary to the practice of the ancients as their character is dissimilar. The orders are employed merely as decoration, and then only for the separate stories of an edifice, or for distinct compartments of a front. Hence they are invariably micro-style, and are still further reduced in height by being placed on tall pedestals, and look all the smaller owing to the spacious proportions of the windows between them. In fact they are to be regarded only as accessories and decorative filling-up, for they have scarcely even the apparent character of columniation. In point of design, too, they retain little of the orders after which they are named: with the exception of one or two distinctive marks, such as the Doric triglyphs, and the forms of the respective capitals, they are all assimilated in character, the Doric being frequently quite as slender and as much embellished or more so than the Corinthian. Pedestals are mostly panelled and filled in with ornament, the panels themselves being multiplied in a variety of patterns. The shafts of columns are frequently enriched with one or more bands (either sculptured or plain), and the lower part of the shafts is often covered with arabesque carving. Pilasters are similarly treated—sometimes banded, sometimes panelled, and frequently filled in with arabesques or other ornaments, among which raised facetted blocks are very common ones. Entablatures are almost invariably made to break over columns, and are so crowded with mouldings and other carvings as to have the look of being all cornice. Orders are usually applied only to parts of a front; for instance, the centre, which is marked out as a lofty frontispiece or portal ornamented with several tiers of columns, and thus not only distinguished from the rest, but in many instances rendered quite distinct from it, all besides being comparatively genuine Tudor, without any intermixture of foreign elements. Even where such is not the case, the Tudor physiognomy manifests itself in windows and bays, which last are almost as peculiar to our English architecture of the period as small circular towers and turrets with conical or spire-like roofs are to that of Flanders and France. Although square-headed, and without tracery of any kind, the windows retain a good deal of the latest Gothic or perpendicular character, being divided by mullions and transoms into numerous compartments after the manner of panelling, a mode that freely admits of a window being made of any extent; and not only are single windows sometimes exceedingly spacious, but they are put so closely together as to render the whole of a front nearly all window. This fashion, which however is only an occasional variety of the style, is strikingly exemplified by Hardwick, Derbyshire, and by what is called "the Duke's House," at Bradford, Wilts. The front of this latter building is made up entirely of windows and bays, in a manner that would be too monotonous, were not the plan-line broken by semicircular projections being thrown out, as smaller bays, from the larger ones. Thus the design acquires a pleasing playfulness of form; and it is besides not only marked by perfect regularity of composition, but also by a certain compactness, the windows not having the appearance of being intended for separate openings squeezed together for want of more space. The parapets upon the bays, consisting of fanciful openwork, enhance the general richness of effect, and both they and the parapetted terrace serve to indicate what are pleasing peculiarities in the style. A more characteristic Elizabethan mansion is Wollaton, Nottinghamshire, of which we give an engraving. Among the most magnificent palatial residences of this period are Longleat, Burleigh, Hatfield, Holland House, Kensington, and Hardwick, mentioned above. The building here given by way of specimen affords a good example of the characteristic Elizabethan gable, a feature so singularly diversified that to exhibit only the leading varieties of it would require a series of cuts, beginning with the simplest and proceeding to the most complex forms. We give one other example of an Elizabethan gable; but it is necessary to say that almost every imaginable combination of curves, both concave and convex, with straight lines and angles, are to be met with in gables of this period. Differently shaped gables often occur in the same building, and produce great effect of outline, which is increased by embellished parapets, with balls and other ornaments upon them, by small domes on turrets, and by chimney-shafts, all which, mingled together in glorious confusion, often give an air of picturesque magnificence to what are otherwise rather plain and homely structures, and impart animation to what would else be lumpish masses. In like manner, porches and balustraded terraces often give much character to the lower part of a building, while the upper may be comparatively flat and uninteresting.



Wollaton House, Nottinghamshire.



[Gable Scroll-work, from Richardson's 'Elizabethan Architecture.']

The plan of an Elizabethan manor-house is often that of two projecting wings and a central porch,—so often, indeed, that it has been supposed that it was intended, in compliment of Elizabeth, to represent the letter E, the initial of her name: a not unlikely thing, as it was not unusual to make the plans of buildings allusive. John Thorpe, the great English architect of the Elizabethan age, designed a house for himself which was to take the form of his own initials, J. T.: the drawings are in the Soane Library. To the internal characteristics of the Elizabethan style belong spacious bay-windows; long and ample galleries, but generally of low proportions; massive and elaborately sculptured chimney-pieces; screens of similar character, either with open arches or doors; wainscoted and panelled walls; ceilings highly enriched, and sometimes arched, and entirely covered with scroll-work foliage; and wide staircases with richly carved balustrades, and heraldic figures of animals at the angles, were important features in the general design.

The prevailing character is that of heaviness and stateliness, on which account it is ill-suited for literal imitation at the present day, especially for houses upon a moderate scale, or for small rooms. In external architecture many of the defects of detail are merged in the picturesque impressiveness of the whole; but a similar degree of capriciousness and heaviness brought near to the eye within a room, is apt to strike chiefly as too rudely grotesque and ponderous; besides which it is an expensive style for internal finishings, for though it will very well bear to be greatly refined upon, it hardly admits of being simplified, decoration even partaking of gorgeousness being almost indispensably necessary to conceal the native uncouthness of both forms and proportions. Still, a judicious modification, or rather perhaps a free development, of the style is well adapted for brick and stone, such contrast of colour seeming natural to it, and serving to bring out the several parts more distinctly. We hardly need observe that the brick ought invariably to be red, and of superior quality and execution; for white or yellow bricks are so far from producing a similar effect, that they have both an insipid and mean appearance, the building seeming at a distance to be of stone, and when approached discovered to be of an inferior material. The brickwork itself is often variegated by the intermixture of darker bricks, so disposed as to form a regular pattern on the walls, generally consisting of intersecting diagonal lines. There are also many instances of brick alone being employed, the ornamental members being formed of moulded bricks; and though the effect is comparatively sombre, it is by no means unpleasing.

[Staircase at Claverton, Somersetshire, from Richardson.]

(Richardson, *Architectural Remains of the Reigns of Elizabeth and James*; Shaw, *Elizabethan Architecture*; Nash, *Old English Mansions*, &c.)

ELL (Ulna), a measure of length now almost disused. "It is properly," says Ducange, "the length between the ends of both the extended hands, though Suetonius makes it to be only one cubit." It is not worth while to attempt to follow a measure of secondary importance through its various changes, and this measure in particular has denoted very different lengths in different countries. The three ells which have preserved a place in our arithmetical works, namely, the Flemish, English, and French ells, are respectively three, five, and six quarters of a yard.

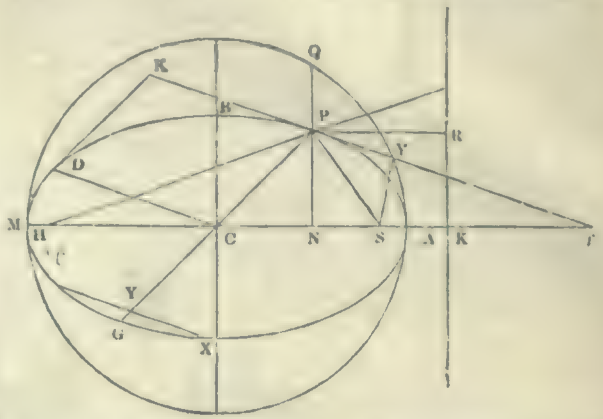
ELLAGIC ACID ($C_{14}H_2O_7,HO$). This acid exists in the gall-nut along with gallic acid; and they are deposited from the aqueous infusion in the state of a yellowish crystalline mass. The two acids are separated by boiling water, which dissolves the gallic acid, and leaves the ellagic unacted upon, but mixed with a little gallate of lime. By treatment with a weak solution of potash the ellagic acid is dissolved, and the gallate of lime remains insoluble; the ellagate of potash is then treated with hydrochloric acid, which uniting with the potash, precipitates the ellagic acid in a pulverulent state. Ellagic acid is also a constituent of certain intestinal concretions which occur in the wild goat, deer, &c., of central Asia, and termed bezoars. Hence this acid is sometimes called *bezoaric acid*.

The properties of this acid are the following. It is of a light fawn colour. It is insipid, sparingly soluble in boiling water, and reddens litmus paper slightly. When heated in close vessels it decomposes, yielding a yellow vapour, which condenses in crystals of the same colour. This acid becomes of a blood-red colour by digestion in nitric acid, and is converted afterwards into oxalic acid. It unites with potash, soda, and ammonia, to form neutral salts; the two first are insoluble in water, except when an excess of base is present; and the ellagate of ammonia does not dissolve under any circumstances. Its acid powers are weak, for it is incapable of decomposing the alkaline carbonates. [BEZOARS.]

ELLIPSE (ἔλλειψις). This curve, which is one of the CONIC SECTIONS, ranks next in importance to the circle (which is in itself an extreme form of the ellipse) and the straight line. We shall here consider the ellipse independently of the other conic sections, and simply state some of the most remarkable properties which can be exhibited without algebraical symbols.

1. Let two any points S and H be taken, and their distance bisected in C. Set off CA and CM, equal lines, each greater than CS, and let a point P move in such a manner that HP and PS together are always equal to AM. The curve described by the point P is an ellipse.

2. CA is called the *semi-axis major*, CB the *semi-axis minor*, C the *centre*, S and H the *foci*, SP and HP the *focal distances* of the point P, CP the *semi-diameter* of the point P, and CD (drawn parallel to the tangent PT) the *conjugate semi-diameter* or *semi-conjugate* of CP. Also the fraction which CS is of CA is called the *eccentricity* of the ellipse.



3. Let SA be to AK as CS to CA. Then KR is called the *directrix* of the ellipse, and SP is to PR as SA to AK.

4. The tangent PT bisects the angle made by SP and the continuation of HP.

5. CA is a mean proportional between CN and CT.

6. If, A and M remaining the same, the figure of the ellipse be altered by varying S and H, the tangents drawn through the several points in which the ellipses cut NQ will all pass through the same point T of the axis. The circle AQM is the extreme form of the ellipse, when S and H meet in C: and the tangent at Q passes through T.

7. Wherever the point P may be taken, NP bears to NQ the same proportion as CB to CA, and so does the area ANP to the area ANQ.

8. The perpendicular let fall from either S or H upon PT must cut it in a point of the circle AQM.

9. If CD be parallel to the tangent at P, then CP is parallel to the tangent at D.

10. The parallelogram PCDK is equal to the rectangle of BC and CA, and the sum of the squares on PC and CD is equal to the sum of the squares on AC and CB.

11. The square on PN is *less* than the rectangle contained by AN and NM in the proportion of the square on CB to the square on CA.

12. PG bisects every line parallel to CD which is bounded at both ends by the ellipse, and the square on XY is to the rectangle contained by GY and YP in the proportion of the square CD to that on CP.

13. The square on CD is equal to the rectangle contained by SP and PH.

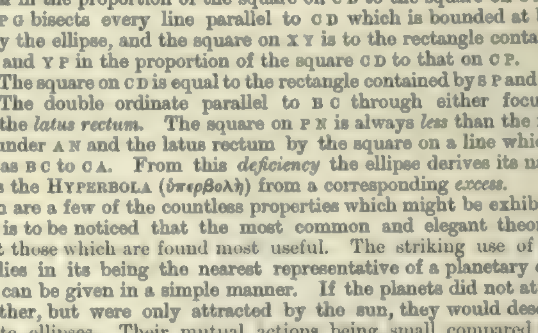
14. The double ordinate parallel to BC through either focus is called the *latus rectum*. The square on PN is always *less* than the rectangle under AN and the latus rectum by the square on a line which is to AN as BC to CA. From this *deficiency* the ellipse derives its name, as does the HYPERBOLA (ὑπερβολή) from a corresponding *excess*.

Such are a few of the countless properties which might be exhibited. But it is to be noticed that the most common and elegant theorems are not those which are found most useful. The striking use of this curve lies in its being the nearest representative of a planetary orbit which can be given in a simple manner. If the planets did not attract each other, but were only attracted by the sun, they would describe absolute ellipses. Their mutual actions being small compared with that which the sun exerts, they consequently move in ellipses *very nearly*. Hence the utility of the ellipse in astronomy; but at the same time the properties of the curve which facilitate the investigation of the heavenly motions present nothing so striking as those which we have given.

The reader who is not versed in geometry must remember that, though an ellipse be an *oval*, yet an oval is not necessarily an ellipse. A figure may be formed by arcs of circles which shall have the appearance of an ellipse without possessing any of its properties.

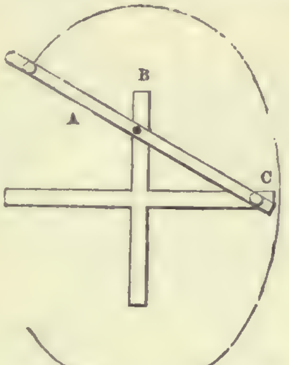
ELLIPSOID. [SURFACES OF THE SECOND DEGREE; SPHEROID.]

ELLIPTIC COMPASSES, the name given to any machine for describing an ellipse. We shall only mention two contrivances of the



kind out of a large number which have been proposed. The first is the simple and rough method suggested by the first property in the article ELLIPSE. Let two pins be fastened to the paper at the points in which the foci are to lie, and let a thread, equal in length to the proposed major axis, have one end tied to each pin. Then if a pencil move in such a way as to keep the thread always stretched, it will describe an ellipse.

The second method is as follows: it is known that if any two fixed points in a straight line A be made to move along two other straight lines, B and C, then every other point in A will describe an ellipse. If then two grooves be made (at right angles to each other, for convenience), and if two pins attached to a ruler be made to travel in the grooves, the motion of the ruler will make any pencil attached to it trace out an ellipse. The distances of the pencil from the two pins will be the semiaxes of the ellipse. If the pins be attached to the ruler by clamping screws their distance may be altered, and the instrument may be made to describe any ellipse within limits depending on the length of the ruler and of the grooves.



ELLIPTIC FUNCTIONS, or ELLIPTIC TRANSCENDANTS. This is no subject for a Cyclopædia, except in a very limited sense. We can only undertake here to describe the general character of the subject.

If we had passed direct from algebra to the differential calculus, without any consideration of logarithmic or trigonometrical quantity [TRANSCENDENTAL], we should have found ourselves stopped in the integral calculus by want of language in which to express the integral of such a function as

$$\frac{dx}{\sqrt{(a+bx+cx^2)}}.$$

It would no doubt have been found (since the same difficulty has been conquered in a more complicated form in the subject of the present article) that all such integrals could be expressed by means of those of

$$\frac{dx}{\sqrt{(a^2-x^2)}} \text{ and } \frac{dx}{\sqrt{(a^2+x^2)}};$$

and the connection of the former of these with the arc of a circle, and of the latter with logarithms, the properties of the functions called sines and cosines, tables of their values, with a complete system of trigonometrical formulæ, would speedily have followed. From this mode of arriving at a new set of transcendentals we are saved by having the science of trigonometry already prepared on a geometrical basis, in connection with the properties of the circle. But we have no such preparation founded on the ellipse, a curve which is an extension of the circle. Nor is there any connection between the arc of an ellipse and the excentric anomaly, the angle of which is the extended representative of the angle at the centre in the circle, except by means of a definite integral. In fact, a being the semi-axis major, e the excentricity, ϕ the excentric anomaly, and s the arc, we have

$$s=a\int\sqrt{(1-e^2\cos^2\phi)}\,.\,d\phi.$$

The integral calculus is, as yet at least, the only manner in which the arc of an ellipse can be approached: accordingly, a large class of integrals, closely related to, and containing among them, the expression for the arc of an ellipse, have received the name of elliptic functions.

By an elliptic function is meant any integral of the form

$$\int\frac{\text{P}\,dx}{\sqrt{(\alpha+\beta x+\gamma x^2+\delta x^3+\epsilon x^4)}},$$

in which P is a rational function of x. This can be shown to depend for its determination upon the form

$$\int\frac{\text{Q}\,d\phi}{\sqrt{(1-e^2\sin^2\phi)}},$$

in which Q is a rational function of $\sin^2\phi$, and e is less than unity. This, again, can be shown to depend upon

$$\int\frac{\text{A}+\text{B}\sin^2\phi}{1+n\sin^2\phi}\cdot\frac{d\phi}{\sqrt{(1-e^2\sin^2\phi,)}},$$

which in every case depends upon one or more of the three following forms:—

$$\int\frac{d\phi}{\sqrt{(1-e^2\sin^2\phi)}} \quad \int\sqrt{(1-e^2\sin^2\phi)}\,.\,d\phi$$
$$\int\frac{1}{1+n\sin^2\phi}\cdot\frac{d\phi}{\sqrt{(1-e^2\sin^2\phi)}},$$

which are called functions of the first, second, and third species. Every elliptic function represents the arc of some algebraical curve.

The earliest researches into the integrals connected with the arcs of an ellipse or hyperbola are those of Maclaurin, in his treatise on Fluxions, and of D'Alembert, in the Berlin Memoirs for 1746. Fagnani, in 1750, showed how two arcs of an ellipse might be assigned in an infinite number of ways, which should have for their difference an algebraical expression. Euler, in 1761, showed how to assign the complete integral of certain differential equations of which the terms are separately nothing but elliptic functions. Landen, in 1755, showed that every arc of an hyperbola can be obtained by means of two arcs of an ellipse. Lagrange, in 1785, gave a general method for approximating to the values of elliptic functions of all kinds.

But those to whom it is due that the theory of elliptic functions has become a distinct and important branch of the integral calculus, with general formulæ which have made it an extended form of trigonometry, are Legendre, Abel, and Jacobi. Of these, the first almost devoted his life to the subject. His various memoirs, and his latest extensions of them, are contained in the two following works:—

'Traité des Fonctions elliptiques et des Intégrales Eulériennes,' 4to, Paris, vol. i., 1825; vol. ii., 1826; vol. iii., containing three supplements, 1828; and 'Exercices du Calcul Intégral,' 3 vols. 4to, Paris, 1811. Both these works contain extensive tables for the calculation of the functions.

The memoirs of Abel, the substance of some of which are in the third volume of Legendre, were originally published in Crelle's journal, and are now collected in his works, which were published in French, 'Œuvres de N. H. Abel,' collected by B. Holmboe, Christiania, 2 vols. 4to, 1839. Jacobi's work is 'Fundamenta nova theoriæ functionum ellipticarum, auctore D. C. G. I. Jacobi,' Regiomonti, 1829, 4to. As to elementary works, there is some account of Legendre's first memoirs in the second and third volumes of Leybourn's 'Mathematical Repository:' several works on the integral calculus, that of Mr. Hymers in particular, contain the first elements. There is a work on the subject expressly by M. Verhulst, printed in Belgium; and there is an article on elliptic functions and definite integrals in the 'Encyclopædia Metropolitana.'

Since the publication of the 'Penny Cyclopædia' many researches have been made, which not only illustrate the analogy between elliptic functions and ordinary trigonometry, but advance into higher views of transcendental integration, and foreshadow the time when elliptic functions themselves will be but a particular case of a higher theory. There is an able report on the progress of this branch of analysis up to near 1846, by the late Robert Leslie Ellis, in the Reports of the British Association for 1846. There is also an elementary work, or at least as nearly elementary as its mode of view will permit, by MM. Briot and Bouquet, 'Théorie des Fonctions Doublement périodiques, et, in particulier, des fonctions elliptiques,' Paris, 1859, 8vo.

ELLIPTIC POLARISATION is the name given to a peculiar modification of polarised light, which is thus designated because, according to the undulatory theory, the ethereal particles describe ellipses in the case of light so modified. The term was, however, employed by Sir David Brewster for another reason ('Phil. Trans.,' 1830); and elliptically polarised light is recognisable as such by experimental characters independently of any theory as to its nature.

If ordinary polarised light, which, in contradistinction to light that is elliptically polarised, is called *plane-polarised*, is reflected from the surface of glass or any other transparent medium, the reflected light (neglecting for the moment certain small deviations to be noticed presently) is plane-polarised, having all the characters of light polarised by reflexion from glass at the proper angle, or by transmission through a Nicol's prism, &c. If, however, plane-polarised light be similarly reflected from a metal, the reflected light will no longer be found to be plane-polarised, unless the plane of incidence be parallel or perpendicular to the plane of primitive polarisation, or the angle of incidence be very small or very near 90°. In general, on being examined by an analyser, such as a Nicol's prism, which is made to rotate, the light is never extinguished, but merely passes through a minimum, being a maximum and a minimum alternately at every quarter revolution. So far it resembles partially polarised light, such as common light reflected from glass at an angle differing from the polarising angle, or reflected from a metal. But the two kinds are in reality totally different, as may be seen at once on examining them by a Nicol's prism capped with a plate of calcareous spar, cut perpendicularly to the axis, which is turned towards the light to be examined. Partially polarised light (or, to speak more precisely, partially plane-polarised light), on being examined in this way, shows the well known rings of a uniaxal crystal, diluted with a uniform light spread over the field; whereas the light obtained by reflecting plane-polarised light from a metal, as above described, shows a system of rings as vivid as those produced by plane-polarised light, but of a different character.

Light is capable of receiving the same modification by total internal reflexion. If plane-polarised light be reflected internally from glass at an angle of incidence exceeding the critical angle (or that at which total reflexion begins), then, unless either the plane of polarisation be parallel or perpendicular to the plane of incidence, or the angle of incidence be very near one of the two limits, the critical angle and 90°, the reflected light will be found to be elliptically polarised, agreeing in its characters with light which, having been previously plane-polarised, has been reflected from metal.

But elliptic polarisation may also be produced without reflexion, in a manner which indicates at once its real nature. If plane-polarised light be transmitted through a thin plate of mica or selenite, then, unless either the principal axes of the plate are parallel and perpendicular to the plane of primitive polarisation, or else the thickness of the plane has one or other of a set of determinate values, the transmitted light will be found to be elliptically polarised, having the same characters as before.

Now, in this case, we know that the primitive plane-polarised light is divided in passing through the crystal into two pencils, which are polarised respectively in the principal planes of the plate, and which after emergence run on together, having been unequally retarded by passing through the plate. It appears, then, that elliptic polarisation, whatever it may be, is capable of being produced by the interference of two plane-polarised beams, of which one is retarded relatively to the other.

If, then, we adopt the undulatory theory of light, and the doctrine of transversal vibrations, we shall be able to form a perfectly clear conception of the nature of elliptically polarised light. According to this doctrine, plane-polarised light consists of vibrations which are rectilinear, and perpendicular to the ray (confining our attention to the case of propagation *in vacuo*, or in a singly refracting medium), and which, like all the phenomena relating to such light, are symmetrical with respect to the plane of polarisation, and are therefore either in or perpendicular to that plane. Opticians are still divided in opinion on the point last mentioned; but for the explanation of the phenomena with which we are at present concerned, it is a matter of perfect indifference whether the vibrations are supposed to be parallel or perpendicular to the plane of polarisation, though, from considerations into which we cannot here enter, the latter view appears the more probable.

Let the ether be referred to the rectangular axes of x, y, z, the axis of x being measured in the direction of propagation, and those of y, z along the principal planes of the plate; and let the plane of primitive polarisation be inclined at angles a, $90° - a$, and to the axes of y, z. Then, if we represent the vibration by $a \sin p\,(vt - x)$, and take y, z to denote the vibrations belonging to light polarised in the planes of $x\,y$ and $x\,z$, the resolved vibrations belonging to light polarised in the principal planes of the plate will be represented by

$$y = a \cos a \sin p\,(vt - x)$$
$$z = a \sin a \sin p\,(vt - x).$$

On emerging from the plate the phase of former vibration will be accelerated or retarded relatively to the latter (suppose accelerated) by δ, and putting ϕ for $p\,(vt - x) +$ a quantity the same for both, we may represent the vibrations in the emergent light by—

$$y = a \cos a \sin (\phi + \delta)$$
$$z = a \sin a \sin \phi.$$

To find the equation to the curve described by the ethereal particles we must eliminate ϕ from these equations, which gives

$$(\sin a.y - \cos a \cos \delta.z)^2 + \cos^2 a \sin^2 \delta.z^2 = a^2 \sin^2 a \cos^2 a \sin^2 \delta,$$

the equation of an ellipse, which, when $\delta = 90°$ or an odd multiple of 90°, and $a = 45°$, becomes the circle

$$y^2 + z^2 = \tfrac{1}{2}\,a^2.$$

Hence the ethereal particles move in general in ellipses, which is the reason why light thus modified is called by undulationists elliptically polarised. It would lead us too far to follow into their details the mathematical characters of the vibrations which, according to the undulatory theory, constitute elliptically polarised light, for which the reader is referred to Airy's 'Tracts,' or other standard works on physical optics.

We are led then to infer that, in the case of light reflected from a metal, or totally reflected internally in glass, the phase of vibration of the component of the reflected light which is polarised in the plane of incidence is changed relatively to that of the component polarised in the perpendicular plane. In the case of metallic reflexion the former component is accelerated, in the case of total internal reflexion retarded, relatively to the latter. This is shown at once by the character of the rings of calcareous spar, observed as above explained, by noticing in which pair of opposite quadrants (whether the first and third or the second and fourth) the action of the spar, as a doubly refracting crystal, compensates the change of phase due to reflexion, the spar being known to be a negative crystal.

From his expressions for the intensity of reflected polarised light, which in the case of total internal reflexion become imaginary, Fresnel deduced mathematical expressions for the change of phase which accompanies total internal reflexion. Guided by these expressions he was led to construct a rhomb of glass (now known as Fresnel's rhomb), a section of which is of the form of a long parallelogram, the acute angles of which are determined by an equation involving the refractive index of the glass, and which for the glass which he employed came out about 54° 37′. Light entering perpendicularly one of the shorter faces emerges perpendicularly at the opposite, after suffering two total internal reflexions at the long faces. The angle of the rhomb is determined by the condition that the difference of phase of the components polarised in and perpendicular to the plane of incidence is one eighth of an undulation for each reflexion, and therefore one-fourth of an undulation for the two. Such a rhomb is much used in experiments on polarisation; but it is essential that the glass should be thoroughly annealed, a condition for want of which many rhombs made for the purpose are worthless. If plane-polarised light is transmitted through such a rhomb, the plane of reflexion in the rhomb being neither parallel nor perpendicular to the plane of polarisation, the emergent light is elliptically polarised; if through two such rhombs placed with their planes of reflexion parallel, the emergent light, in accordance with the prediction of theory, is found to be plane-polarised, the plane of polarisation being equally inclined with the plane of primitive polarisation to the plane of reflection in the rhombs, but on the opposite side. If, with a single rhomb, the plane of reflexion is placed at 45° to the plane of primitive polarisation, the emergent light is of the kind in which the ellipse of theory becomes a circle, and which is called circularly polarised. Such light is characterised experimentally by presenting the same appearance on analysation when the analyser is turned round, while it differs from common light by presenting a peculiar and perfectly vivid system of rings with calcareous spar, or, if this mode of observation be preferred, by being converted into plane-polarised light by transmission through a crystalline plate of proper thickness, or through a Fresnel's rhomb.

Whether the plane of reflexion in the rhomb be inclined 45° to the right or to the left of the plane of primitive polarisation, we obtain circularly polarised light; but the light so obtained in the two cases differs both theoretically and experimentally in a character of right-handedness or left-handedness. Experimentally the difference is at once recognised by means of a plate of calcareous spar and a Nicol's prism, by noticing whether the rings of the first and third quadrants are pulled out, and those of the second and fourth pushed in, or *vice versâ*. Elliptically polarised light in like manner may be either right-handed or left-handed.

On the subject of metallic reflexion, the reader is referred to Sir David Brewster's well-known paper in the 'Philosophical Transactions' for 1830; and to an elaborate memoir by M. Jamin, in the 'Annales de Chimie,' ser. iii. tom. 19, p. 296. M. Jamin has also ('An. de Ch.,' tom. 29, p. 263) investigated, in the case of transparent substances in general, the change of phase about the polarising angle, or, more properly, the angle of maximum polarisation, which Mr. Airy had observed in the case of the diamond. ('Cambridge Philosophical Transactions,' vol. iv. p. 409.)

ELLIPTIC REFLECTOR. If a pencil of light have its focus at one of the foci of an ellipse, rays diverging from such focus striking upon the ellipse, or on any surface with which the ellipse would coincide, would be reflected to the other focus. A mirror formed into the figure of an ellipsoid, or portions thereof, acting on this principle is called an *elliptic reflector*. [LIGHT.]

ELLIPTICITY, a term used in the theory of the figure of the earth. It means the fraction which the excess of the axis major over the axis minor of an ellipse is of the axis minor itself. Thus, if the axis major be 9 and the axis minor 7 the ellipticity is $\frac{2}{7}$. This term must not be confounded with the *excentricity*, a word in much more common use. If a and b be the semiaxes major and minor, and if e be the excentricity and E the ellipticity, then

$$\mathrm{E} = \frac{a - b}{b},\ e = \sqrt{1 - \frac{b^2}{a^2}}$$

if b and a be nearly equal, $e^2 = 2\,\mathrm{E}$ nearly.

ELM, *Economical Uses.* The wood and other parts of the elm-tree are applied to a great variety of useful purposes in the arts of life, both domestic and trading. The timber, being hard and fine-grained, is valuable for ship-building, such as in making the blocks and dead-eyes, but especially the keels, which are made in one piece if the keel be not very long. Elm is used for the naves of wheels; in London for coffins; for water-pipes and troughs; and for conveying the Cheshire brine from the salt-springs to the evaporating pans. Knotted and twisted varieties of the wood are much sought by cabinet-makers for ornamental purposes. Elm veneers are sometimes dyed to imitate mahogany, by means of a dye of dragon's blood, alkanet root, aloes, and spirits of wine. As fuel, and as a material for charcoal, the elm is rather inferior to the beech. The ashes are rich in alkali. The leaves and young shoots are used in some parts of the Continent to feed cattle and pigs, and even silkworms. In some parts of Russia the leaves are used as a substitute for tea. The bark is useful as an astringent medicine, and the inner bark for making nets and ropes. The bark and leaves yield an adhesive substance, which may be used as glue. The bark, kiln-dried and ground, and mixed with flour, is used by some of the poor in Norway for bread.

The above details relate to the common elm. The Scotch or wych-elm is equally useful. The timber is much prized by ship-builders, boat-builders, block-makers, pump-makers, cartwrights, cabinet-makers, and coach-makers. For floor-timbers of ships, naves and shafts of vehicles, swingle-trees for heavy gun-carriages, dyers' and printers' rollers, wheelbarrows, and the handles of agricultural implements, the wych-elm is much used, because it cleaves well without splintering. The bark, which is very tough, and strips off easily, is applicable to a great variety of useful purposes.

ELOCUTION. [ORATORY.]

E'LOGE, in the French language means praise, being derived from the Latin *elógium*, and that from the Greek *eulógia* (εὐλογία). It has become the name of a considerable branch of French literature, which comprehends panegyrical orations in honour of distinguished deceased persons. It is the custom when one of the members of the French or other academies dies, and a new member is appointed in his place, for the new member to deliver a panegyrical oration on the labours and other merits of his predecessor. These éloges are generally printed and published, and although they are mostly written in a florid rhetorical style, still many of them are really interesting biographies. Such, for example, are the éloges written by Cuvier and Arago on several of their brother academicians. [CUVIER and ARAGO, in BIOG. DIV.] The custom of writing éloges of deceased persons is not confined to members of academies. Bailly wrote 'Eloges de Charles V., de Molière, de Corneille, de l'Abbé de la Caille, et de Leibnitz,' Berlin, 1770. The Italians have also 'Elogii degli Uomini Illustri Toscani,' 3 vols., fol., Firenze, 1766–70, and many other similar compositions.

ELONGATION, an astronomical term for the angular distance between two heavenly bodies as seen from the earth. Custom has confined it to the case in which both bodies are in the solar system, and one of them is generally the sun. Thus we speak of the *distance* of two fixed stars, and of the *elongation* of Mercury from the sun.

ELOQUENCE. [ORATORY.]

ELUL, אֱלוּל, the last month of the civil year of the Hebrews, coinciding, when earliest, nearly with our August; when latest, with our September. The origin of the name is doubtful: older Hebrew philologers derived it from the word אֱלִיל, "nothing," because nothing remains in the ground at that season! Recent savants more wisely profess their ignorance. Benfey's derivation from the Zend *Haurvat*, through the old Persian mouth *Chordad*, would seem at first sight absurd, a mere result of dexterous letter-shifting; but if we look at the not unfrequent interchange of *d* and *l* (Οδυσσευς, Ulysses; lacryma, δακρυ, &c.), particularly in the case of the combination *rd* in old Persian, as in *thurda*, a year, modern *sal*; *warda*, a rose, modern *gul*; we may be induced to suspend our condemnation; more especially when we consider that Chordad was the sixth month in the Persian calendar, as Elul was in that of the Jews until the middle of the 4th century, A.D. It is moreover well known that the names of the months now in use do not occur in any of the books of the Bible written before the captivity, which ultimately brought the Jews under the domination of Persia. Elul is found in the 6th chapter of Nehemiah, 15th verse, where the completion of the walls of Jerusalem is recorded; it is also found in the apocrypha, in Maccabees xiv., 27.

Two festivals are held in this month; the first is that of the Dedication of the walls of Jerusalem by Nehemiah, on the seventh day of Elul; the other is that of the expulsion of the Greeks, on the seventeenth. Some Jews observe a fast on the seventeenth day, in memory of the death of the spies who brought back an evil report of the Promised Land; Numbers, xiv., 37.

Elul has only twenty-nine days.

ELUTRIATION, the process of separating substances reduced to powder, when of different specific gravities, by means of water. It is also employed as a method of reducing any one substance to a fine powder; thus the creta præparata, or prepared chalk of the 'London Pharmacopœia,' is prepared by mixing finely-powdered chalk with water, stirring the mixture, and while it is yet turbid allowing the upper portion of the water to run off; and when this is allowed to settle, the chalk or any other substance similarly treated settles in a very fine powder. By the process of elutriation ores, especially those of tin, are separated from earthy matter.

ELY'SIUM, the name given by the ancient Greeks and Romans to the abode of the righteous after death. They fancied that there was, somewhere to the west, a region blessed with perpetual spring, clothed with continual verdure, enamelled with flowers, shaded by pleasant groves, and refreshed by never-failing springs, where the souls of the good repaired, and where they enjoyed each other's society. (Virgil, 'Æneid,' vi., with which compare the notion of Elysium in the 'Odyssey,' iv., 563.) The "Islands of the Blest" was another name for this favoured region, which some placed in the midst of the ocean in the farthest west, others in some inaccessible spot in the middle of Asia or Africa. From this notion the appellation of Elysian Fields came to be given to certain delightful secluded spots, such as the strip of land on the northern shore of the Mare Morto, or the inner part of the harbour of Misenum near Naples. It seems to have been originally a vast cemetery, planted with trees and adorned with tombs; but the imagination of the poets confounded the repository of the perishable bodies with the abode of the immortal souls. The Mare Morto was the Acheron through which the dead were wafted to their final abode. Those ancient philosophers who had more spiritual notions of the nature of souls discarded the vulgar idea of the Elysium being in any part of our globe, and placed the abode of the departed in the heavens or firmament. (Cicero, 'Somnium Scipionis.')

EMANCIPATION, Emancipátio. To understand the legal effect of emancipation by the Roman law, it must be premised that all children born in lawful marriage were said to be in the father's power, as well as all his son's children so born before the son was emancipated; and no person who was in the power of another could acquire any property of his own. (Gaius, ii. 86, &c.) Whatever property, then, a son acquired while in his father's power strictly belonged to his father. If the son was by will appointed heir (hæres in the Roman sense), he could not accept without his father's consent, and all that he took was for the benefit of his father: the same rule held as to a legacy. It is unnecessary here to mention the exceptions to the general rule above laid down, or to describe the father's power over the son's person. "There is hardly any nation," observes Gaius (i. 55), "in which fathers have such power over their children as we have." The rigour of the ancient Roman law, however, was gradually relaxed, though the remarks of Gaius, who wrote at least after the time of Antoninus Pius, show that it was not then entirely fallen into disuse. The father's power was dissolved by his natural death, and also by the civil death of the father or the son. (Gaius, i. 128.)

Emancipation was the act by which the power was dissolved or released in the lifetime of the father; and it required the consent of both parties. The emancipation, which was made according to the Laws of the Twelve Tables, was effected by an imaginary sale from the father to another person. In the case of a son, this sale was made three times, as if the father were selling a slave, and the person to whom the sale was made, who of course was some friend, manumitted the son after each sale. After each of the first two sales, the son, being manumitted, became again in his father's power; but the last manumission was final, and extinguished all the father's paternal rights. It was however usual for the son, after the third sale, to be resold to his natural father, who then manumitted him, and thus acquired the rights of a patronus over his emancipated son, which would otherwise have belonged to the purchaser who gave him his final manumission. In the case of a daughter or a grandson, a single sale and manumission was sufficient. (Gaius, i. 132; 'Dig.,' lib. 28, tit. 3, l. 8; 'Cod.,' lib. 8, tit. 49, l. 6; 'Instit.,' lib. i., tit. 12, s. 6.)

The Emancipatio Anastasiana, or that introduced by the Emperor Anastasius, was by Imperial Rescript. ('Cod.,' lib. viii., tit. 49, l. 6.)

The Emancipatio Justiniana was effected by a simple declaration of a father before the proper magistrate, that he released his son from the paternal authority; but the father still retained the rights of a patronus over his emancipated son. (Ibid. l. 6.)

The immediate legal effect of emancipation was, that the person emancipated possessed over his own children the paternal right: he could acquire property, and bequeath it by will. If a son married and had children before he was emancipated, his children were in the power of their grandfather, who could emancipate them without emancipating their father; and such emancipation continued in force after the grandfather's death.

It was also a consequence of emancipation that the emancipated children stood to their father in the relation of strangers, and consequently, in case of intestacy, could not take the parent's property, which could only be claimed by those who corresponded to the legal description of heredes sui, agnati, and gentiles. But this injustice of the civil law (juris iniquitates), observes Gaius, was remedied by the prætor's edict, or, as we should term it, the equity, which was gradually introduced in order to soften the rigour and strict rules of the civil law. [EDICT.] The prætor's edict, however, did not extend to give the same advantage to an emancipated son in succeeding to the property of an intestate brother. The Emperor Anastasius remedied this under certain restrictions; and finally Justinian put emancipated and non-emancipated brothers and sisters and their children on the same footing in all respects as to sharing in the property of a deceased parent or brother or sister. ('Cod.,' lib. vi., tit. 57; 'Instit.,' lib. iii., tit. 5.)

As to emancipation under the Code Napoléon, see liv. i., chap. 3, tit. 10.

EMBALMING. [MUMMY.]

EMBANKMENT, in civil engineering, a mound, or heap of earth, thrown up for the purpose of forming a roadway at a level different from that of the natural surface of the ground; or for the purpose of either regulating the flow of a river or a navigable canal, or of defending low-lying districts from the effects of floods, storms, or high tides in rivers, or upon the shores of lakes or seas. In military engineering, embankments are frequently used to back up the fronts of scarped fortifications, and to form the glacis, the cavaliers, banquettes, caponières, or other earthwork defences; but as the purposes to which embankments are applied in civil engineering are perhaps more important than those connected with military engineering, the former will alone be discussed in the present article.

In designing a roadway, whether for ordinary carriage or railway traction, or in designing a canal, it is desirable, as far as possible, to provide in the work itself for the disposal of the whole of the earth it may be necessary to remove, in order to secure the required conditions of level of the finished surfaces; or, in other words, to make the embankments balance the excavations. This condition very frequently renders it necessary to form very lofty embankments; and the movements these accumulations of earth are likely to produce, or to undergo, render it equally necessary to adopt great precautions in their execution. If, for instance, an embankment should be formed on a compressible or on a shifting subsoil, it may either produce a vertical or a lateral displacement of that surface; or again, if the embankment should have been carried up with undue haste, the loose earth of which it is composed will be exposed to subside, in all probability, in a very unequal manner. Naturally, the precautions to be observed in the various cases thus alluded to, will vary according to the peculiar circumstances affecting them; but the leading principle is the same in all,—namely, that the weight of the material of the embankment must be made to act equally in a vertical direction, and that the tendency to lateral movement should be effectually resisted.

Embankments formed upon peaty subsoils are especially liable to vertical compression; and it is to be observed that, in the majority of alluvial districts, layers of peat are intercalated between the layers of sand, clay, or soft semifluid silt, which constitute the bulk of those deposits. In diluvial, and in many of the clayey series of the older formations, compressible silty beds occur between others of a more resisting character; and if, by reason of the great superincumbent weight, or by any accidental disturbance of the natural conditions of equilibrium of the upper beds, the compressibility of the lower ones should be brought into action, the practical effects produced may become of the most dangerous description. It is, therefore a matter of great importance that borings should be taken all over the area of any intended embankment; and that, if it should be of any great height, the borings should be continued to a considerable depth, especially upon the banks of a river which might be likely to interrupt the continuity of any of the subterranean strata. Very frequently it may also happen that drainage operations may disturb the normal conditions of equilibrium of the intercalated sandy or peaty beds of the alluvial districts referred to above; and in those cases, the subsequent addition of any extraordinary weight, by reason of the execution of an embankment, would require that measures be adopted to limit the range of action of the respective disturbing causes, whether they act above or below the natural surface. Perhaps the best commentary on the principles above stated may be found in a brief description of the practical methods adopted in various countries to ensure the stability of large embankments.

Upon peaty subsoils the whole of the action of the superincumbent weight is frequently resolved into a direct vertical one by means of a double row of sheet piles, which confine the influence of the weight to the precise area so inclosed; or again, as in the case of the embankments executed in Bavaria for the railways carried across the peat bogs of that country, pits are sunk (in the manner of the squares of a chess-board) through the peat, and these pits are subsequently filled in with incompressible materials. In some instances, when heavy buildings (which, of course, act in precisely the same manner as heavy embankments) have been executed upon layers of soft mud of a practically unlimited thickness, they have been laid either upon a wide bed of concrete, or upon a thick bed of fine sand kept from spreading laterally; or they have been founded upon piles driven with their butt ends downwards, as at Brest. The principle observed in all these instances is merely to distribute the weight over a large base; but in Holland, and in many analogous districts, the engineers exercise great skill and ingenuity in the adaptations of means for diminishing the weight of the heart of the embankment,—the portion which precisely would be the heaviest if the bank were executed of solid earth,—by the introduction of layers of reeds, or of fascines. These materials, moreover, tend to distribute the weight over a large area, and they thus produce a double benefit. The sketch given in Minard's 'Traité des Canaux,' &c., of the mode of forming the dykes, or the embankments, across the smaller creeks in the Dutch province of Zeeland, will illustrate the system adopted in the countries above mentioned.

Occasionally the tendency of new embankments to slip laterally is resisted by forming steps in the earth of the subsoil, or by cutting deep trenches at the feet of the respective slopes. It must, however, be evident that the success of these operations must depend upon the nature of the subsoil itself; because, whenever the latter is susceptible of lateral displacement it can serve but little purpose to connect the superincumbent load with it. Stepped seatings, and deep footings have at any rate this advantage, namely, that they resist the passage of water between the natural surface of the ground, and the under surface of the embankment; and therefore, one or the other of them should invariably be resorted to, if there should be any danger from the infiltration of water beneath the seat. Under ordinary circumstances it would be preferable, of course, to form ditches, or drains, for the purpose of intercepting these surface waters; but the additional precautions of stepping, or trenching the feet of the bank, are rarely superfluous. In those cases wherein banks are formed for the purpose of storing large bodies of water, it becomes especially necessary to prevent the passage of the water under the seat of the bank itself; and in all such works (of any considerable magnitude) it is customary to insert what is called a "puddle dyke," or a species of wall of impermeable materials, which is carried through the whole depth of the bank and the porous materials of the subsoil, to the impermeable strata beneath them. Some of the most remarkable works of this description are those lately executed for the catch-water reservoirs of the Liverpool and of the Manchester Water-works, or those executed in America for the Croton Water-works, wherein, by the way, the resistance of the banks to lateral displacement was assisted by the introduction of cribbed or cradle-work, to be noticed hereafter, under WEIR.

Embankments formed upon the sides of running-streams, have to resist not only the tendencies to vertical compression, and to lateral displacement already referred to, and the danger arising from the infiltration of water under their seats, but they have to resist, 1st, the dynamical action of the water at its maximum elevation: and 2nd, the tendency of the current to carry away the materials of which the banks themselves are composed. The former of these conditions will naturally be affected by the height of the water, and, to a great extent also, by its width; for the waves produced in any body of water depend for their height, partially upon the breadth of the surface over which the wind may blow. The latter condition will equally, of course, depend upon the velocity of the current, and the materials which are the most directly exposed to its action must be of such a nature as to obviate any danger of their being displaced by that agent. In the article HYDRODYNAMICS, there will be found a table of the transporting powers of water at different velocities, and the various modes of defending embankments from the action of the waves, or currents, will be discussed under SEA DYKES; RIVER DEFENCES. Of whatever materials such river or sea walls may be externally composed, it is desirable that they should present a very flat slope towards the land side; and that they should be carried up above the highest point to which the waves can reach.

The compression of the materials of an embankment (which is, it must be observed, one of the most important considerations in the execution of such works), must depend mainly upon the mode adopted for the transport and delivery of the materials. Formerly, embankments of small height were executed either by barrow, or cart work, and in regular layers of small thickness; and this mode of execution is still retained in many instances in hydraulic works. But when railways created the necessity for the rapid formation of the colossal embankments, some of which will hereafter be described, it became necessary to introduce a more expeditious, even though less perfect mode of execution. It was for the purpose of meeting this practical requirement of the age that the system of transporting the materials furnished by cuttings to the embankments, by means of railroads and waggons, and of depositing the materials over what is technically called a "flying tip," was introduced. Upon the ancient system, the thickness of the layers of an embankment varied from 18 to 36 inches; whilst upon the modern one, that thickness hardly ever descends below 6 feet, even in forming banks for hydraulic works; and in many instances railway embankments of 30 or 40 feet in height, are made without the intervention of any method for producing a partial compression of the ground. It cannot, therefore, be a matter of surprise that the rate of compression in large embankments should vary between the extreme limits of from $\frac{1}{8}$ to $\frac{1}{12}$ of the finished cubical contents; and it thence becomes necessary both to keep the top of a new bank, formed in the modern style, above the proposed finished height, and to provide for its ultimate compression, by frequent recharges. Especial precautions must be taken against danger from this cause in the case of the embankments required for forming the dams of catch-water reservoirs; and indeed, it would seem to be indispensable that such works should be executed in thin layers, and that each of those layers should be carefully "punned," or rammed; care being taken to prevent the formation of any continuous horizontal bedding in the materials of the bank.

In calculating the respective cubical proportions of the embankments and excavations of a particular work, this fact of the ultimate compressibility of the materials furnished by the latter, and of their primary expansion, must be carefully taken into account. Another practical observation, which perhaps it may be as well to make here, is that embankments formed upon the sloping sides of hills are especially liable to lateral displacement; and that in their construction it is therefore more than usually necessary to step, or trench, the footings or seats, and to provide efficacious means for carrying off the surface or spring waters.

One of the most important details to be considered in forming an embankment is the slope to be given to the sides, for this slope will vary with every description of material employed. Thus, it is found that even in executing the embankments required for supporting ordinary roads or railways (or those which in fact have merely to support a vertical weight), the slope required to be given to loose rubble stone, chalk, loamy sand or gravel, is about $1\frac{1}{2}$ base to 1 in height. Light incoherent sand, and ordinary clay, ought to have slopes of about 2 base to 1 in height; whilst the more unctuous clays, such as the Oxford clay or the London clay, frequently require slopes of as much as 3 to 1, in order to prevent slips. Evidently, however, it must be dangerous to lay down any invariable rules on this subject. The nature of all geological materials is liable to great local varieties; and the conditions of the foundations of an embankment, as well as the purposes the embankments themselves are intended to fulfil, differ in such extraordinary manners that it is not possible to say, *à priori*, the course it would be advisable to adopt in every case. It is the duty of the engineer to examine and to allow for the various disturbing circumstances which may affect the application of the general rules above given.

If it should be necessary at any time to form a bridge, or a culvert, drain, &c., under an embankment of any considerable height, precautions must be taken to prevent any unequal thrusts against the side walls of those structures; and the weight thrown upon their crowns must be deposited without producing any sudden shock of a nature to disturb the brickwork or masonry. Care must also be taken to cover the top and the inner sides of the retaining walls with an impermeable material, in order to obviate any danger to the masonry by the infiltration of water through the superincumbent earth. This precaution is far too much neglected in English engineering works, and there can be no doubt but that the fall of many of the railway bridges recently erected may be accounted for by the gradual removal of the mortar from the joints of the masonry, by the passage of the waters falling upon the exposed upper surfaces. It is singular even that there is no special technical word in our language to express the rendering coat laid upon the top of an arch, such as the French word "*chape.*" Hydraulic lime, hydraulic cement, and asphalte, are much used by foreign engineers in the execution of these "*chapes.*"

In addition to the consideration above referred to, with respect to the amount of compression which may be expected to take place in the materials carried to an embankment, according to the method of transport adopted, it is necessary also to bear in mind the relative cost of those different methods, which naturally will vary according to the quantities of earthwork to be dealt with. It is usually admitted that it is preferable to execute embankments, where the rate of compression may be neglected, by means of barrow-work, when the lead, or distance of transport, does not exceed from 70 to 100 yards; when the lead is between 70 and 180 yards it is most economical to employ carts drawn by men, but at about 150 yards lead it begins to be advisable to employ carts drawn by horses; between the distances of 150 and 300 yards, cart-work by horses is decidedly the most economical: but above 300 yards lead there is an economy in using temporary railroads, and waggons drawn by horses, for transporting the material. In very large embankments, locomotives are sometimes advantageously employed, when the lead attains or exceeds a quarter of a mile; local considerations must, however, often render it advisable to modify the application of these calculations.

Amongst the most important embankments hitherto executed may be cited those upon the banks of the Po, the Loire, the Rhine, Meuse, Scheldt, Thames, Ouse, Nene, the shores of Zeeland, Holland, Friesland, &c., to be noticed hereafter; the embankment upon the Ellesmere Canal, near the Pont y Cysilte; the embankments which close the gorges of the gathering grounds of the Liverpool and Manchester Water-works, &c. Upon some of the railways there are also gigantic works of this description; as, for instance, on the Ulm and Augsburg line, the embankment of Gadelbach, cubing $1\frac{1}{4}$ millions of cubic yards, nearly; that of Tabotsofen, on the same line, cubing $1\frac{1}{3}$ millions of cubic yards; that of Cowran, on the Carlisle railway, cubing $1\frac{1}{10}$ millions of cubic yards; those near Blisworth on the Birmingham railway, of the Pont de Yonne on the Lyon, the Malaunay valley on the Rouen and Havre, the Poincy valley on the Strasburg lines, are of somewhat analagous magnitude.

EMBARGO, the word used to denote the act by which the public authorities of a country lay an arrest on ships to prevent their leaving its ports. On the breaking out of war with any nation it has been usual for the government of each country to lay an embargo upon such of the enemy's ships as are within reach, with a view to their being declared good and lawful prize. During the progress of war, when any expedition is on foot against the enemy, and it is desirable to keep the circumstance from the knowledge of the party to be attacked, it is usual to lay an embargo upon all private vessels, as well those under the national flag as foreign vessels, until the object to be attained by secrecy is accomplished. An embargo may also be laid by the government upon ships belonging to its subjects with a view to their employment for the service and defence of the nation. In all these cases it is clear that embargoes are detrimental to commerce; the only case in which they have an opposite character is when a foreign vessel of war or privateer frequents a neutral port, and is restrained from quitting the same until a certain time shall have elapsed after the departure from the port of any vessel of which it might otherwise make prize.

EMBER-DAYS and WEEKS, certain seasons of the year set apart for imploring the blessing of the Almighty on the produce of the earth by prayer and fasting, observed in the Christian Church as early as the 3rd century. Pope Calixtus, who first directed them to be observed, also ordained that the same seasons should be especially devoted to the preparation of the clergy before their ordination. These seasons are mentioned in the laws both of Alfred and Canute. At first the Ember-days were not uniformly observed by different Churches at the same time; but the Council of Placentia, A.D. 1095, fixed the spring and summer Ember-days to be the Wednesdays, Fridays, and Saturdays after the first Sunday in Lent and Whitsunday; those of autumn and winter upon the same days after the feast of the holy cross (September 14th) and St. Lucia (December 13th). The Sundays immediately following all these seasons are still appointed by the thirty-first canon of the Church of England for the ordination of ministers. The four weeks in which the Ember-days severally occur are called Ember-weeks. Shakspere speaks of Ember-eves. The etymology of Ember-days is uncertain. Some have derived the term from *ember*, ashes; others from ἥμεραι, days; and others from *ymbren*, which in the Anglo-Saxon means a circle or revolution, the Ember-days being set seasons in the course or circuit of the year.

EMBEZZLEMENT, from the old French word *besler*, or *embesler*, to filch, is the fraudulent appropriation by servants and others of money or goods entrusted to their care, or received by them on account of their employers.

By Clerks and Servants.—Is an indictable offence under the 7th and 8th Geo. IV. c. 29, s. 46, and by that statute is declared to be larceny, and punishable with transportation for a term not exceeding fourteen or less than seven years, or by imprisonment for any term not exceeding three years. If the offender be a male he is liable to be once, twice, or thrice publicly or privately whipped (if the court shall so think fit), in addition to such imprisonment. This statute extends to the clerks and servants (both male and female) of all persons, whether in or out of trade, provided they are entrusted to receive moneys for their employers. Notwithstanding the statute declared the offence to be larceny, it was necessary to indict the offenders for the particular offence; and the legal distinctions between larceny and embezzlement being often very subtle, offenders escaped. This was remedied by the stat. 14 & 15 Vict. c. 100, allowing persons indicted for larceny to be convicted of embezzlement, and *vice versâ*.

By Workmen in certain manufactures.—A number of statutes, from the 1 Anne, stat. 2, c. 18, to the 6 & 7 Vict. c. 40, provide against fraudulent appropriations by workmen in woollen, linen, fustian, cotton, iron, and other manufactures, and by colliers and miners.

By Agents, Bankers, Attorneys, &c.—Of moneys and securities, when entrusted to them for any special purpose, is constituted a misdemeanor by the statute 7 & 8 Geo. IV. c. 49, and subjects the offender to transportation, as in the case of clerks and servants, or to fine and imprisonment, in the discretion of the court. Further important provisions for the punishment of frauds committed by trustees, bankers, directors, officers, members of bodies corporate and public companies, and other persons entrusted with property, are contained in the statute 20 & 21 Vict. c. 54.

By Public Servants.—Under the 2nd Wm. IV. c. 4, s. 1, persons employed in the public service and embezzling any moneys or securities entrusted to them are to be deemed guilty of felony, and are punishable in the same manner as clerks and servants for the like offence, except being whipped. Embezzlement of money or stores by officers of her Majesty's forces is provided for by the annual army and marine Mutiny Acts. There are, moreover, several acts relating to the embezzlement of naval and public stores. (See the 55 Geo. III. c. 127, and acts there referred to.) Until the 4 & 5 Vict. c. 56, embezzlement by servants of the Bank of England was a capital felony.

As to bankrupts and insolvents, see BANKRUPT and INSOLVENT.

EMBLEM; in Greek, ἔμβλημα (from ἐν and βάλλειν, to cast in), a thing inserted, inlaid work, mosaic, or the like. [MOSAIC]. In English, an emblem is a figurative representation; a representation which by virtue of association suggests to our minds something not expressed to our senses. For instance, a lion is the emblem of courage, a cock of watchfulness, because watchfulness and courage are qualities commonly associated in our minds with those animals, as their characteristics. So by historical association, without any intrinsic fitness, one thing may become the emblem of another, as the wheel and other instruments of torture are emblems of saints who have perished by them. Any device, however arbitrary, when established by usage as a distinctive mark, may become the emblem and be put for that which assumes it, either in writing or in imitative art; as for instance in Wordsworth's lines:—

> From town to town, from tower to tower,
> The red rose is a gladsome flower, &c.

The red rose is the emblem of the house of Lancaster, though no mention of that house has been made, just as the cross is now the general emblem of Christianity.

EMBLEMENTS, from the French words *emblavence de bled* (corn sprung or put above ground), in its strict signification means the profits of land sown, but in its usual sense it extends to roots planted and other annual artificial profits which arise from the soil, as for example, standing corn, hemp, saffron, flax, hops, and garden produce growing above ground, as melons and cucumbers, all of which annually require either sowing, planting, or manuring at the expense of the tenant, and are not a permanent or natural product of the soil.

By a rule of law founded on public policy, and for the encouragement of husbandry, all persons are entitled to the emblements of land sown by themselves in which they have an uncertain interest, and which is determined either by the act of God, or of the law, between the time of sowing or planting and the severance of the crop.

Thus the representatives of a tenant for life, who dies previous to harvest, are entitled to the growing crops as a compensation for the labour and tillage bestowed on the lands by the deceased. The same rule also exists with regard to a strict tenant at will, if his tenancy is determined by the landlord previously to the corn being reaped, and for this reason, that as the tenant could not know when the landlord would determine his will, he could not therefore make any provision against it, and having sown the land upon a reasonable presumption of taking the produce, the law will not suffer him to be a loser by it. If, on the other hand, a tenant for life or at will puts an end to his occupation by his own act, he will not be entitled to the crops, as no uncertainty can exist on his part, which is the point upon which all cases of emblements rest.

The parochial clergy and their under-tenants, being also tenants for lives, and their representatives, are in like manner entitled to all the advantages of emblements by the 28 Henry VIII., c. 11, sect. 6; and, under that statute they are enabled to bequeath by will grain growing upon the glebe land, manured and sown at their own cost; but for the reason above mentioned, a person who resigns his living is not entitled to the emblements.

Fruit trees which cannot be presumed to be planted in contemplation of present profit, but rather of being permanently useful to a succession of tenants, and grass which grows of itself without annual expense and labour on the part of the tenant, are not included within the meaning of emblements. (Woodfall's 'Landlord and Tenant.')

EMBOSSING is the art of producing raised figures or patterns upon wood, metal, paper, cloth, or other materials, by means of pressure; either applied as a sudden blow, as in a stamping-press, or in a more gradual manner, as by an ordinary screw or hydraulic press, or by revolving cylinders. The pattern is usually produced by forcing the face of the material against an engraved die in which the design is cut cut or otherwise formed in intaglio. Sometimes, when the article to be embossed is in the form of a thin sheet, a counterpart to the die, often made of lead or other soft metal stamped by the die itself, is applied at the back to aid the process. In many cases heat is employed during the operation with great effect.

The embossing of cloth for book-covers—an important branch of this art—and the process of stamping the covers themselves, are noticed under Bookbinding. A beautiful machine is in operation for both embossing and printing silk, cotton, or woollen cloth, paper, or other fabrics, in one or more colours by one operation, by means of three distinct metal cylinders or rollers, either of which may be employed for embossing or printing, or for performing both operations simultaneously. These cylinders are arranged round, and pressed with adequate force against, a central or bed cylinder of paper, round which the fabric to be embossed is caused to pass. A soft cloth or felt is applied round the surface of the paper cylinder to answer the purpose of what a printer technically styles blanketing; and a smooth iron roller is provided to roll in contact with the paper cylinder, so as to remove any impression which it may receive, through the fabric operated upon and the blanketing, from the embossing roller. In embossing paper, however, this impression upon the bed-roller may be of advantage as a counterpart to the embossing roller; and, in such cases, where it will not produce inconvenience in any other operation of the machine, it may be allowed to remain. Whenever this is done, the relative diameters of the bed-roller and the embossing-roller must be exactly proportioned to each other, in order to ensure perfect register, or coincidence between the sunk pattern on the small metal roller and the raised pattern on the larger bed-roller, during every part of their cycle of revolutions. The embossing and printing rollers are made hollow for the admission of steam or red-hot iron heaters; and they are also furnished with apparatus for applying colour to their engraved surfaces in the same manner as the cylinders of an ordinary calico-printing machine. For embossing velvets, plain cloths, and papers, the surface of the embossing roller must be cut so as to leave the pattern or device elevated: such pattern being, consequently, impressed into, not raised upon, the surface of the fabric; while for woollens the device must be excavated, or executed in recess or intaglio. The patterns produced by the former kind of roller, though commonly called embossing, do not strictly accord with the definition above given, which conveys what appears to be the strict sense of the word.

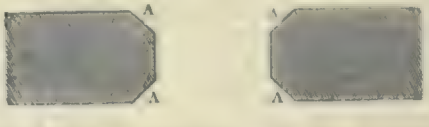
A very curious process of embossing wood was devised some years ago by Mr. Straker. Raised figures on wood, such as are employed in picture frames and other articles of ornamental work, are usually produced either by means of carving, which is an expensive operation, or by applying to the plain surface of the wood ornaments cast or moulded in plaster of Paris or some similar composition—a plan which is not always available. Mr. Straker's invention was intended to facilitate these operations. If a depression be made upon the surface of wood by a blunt instrument which will compress its substance without actually taking away any portion of it, such depressed part will again rise to its original level if the wood be subsequently immersed in water. He therefore proposed to draw the required pattern upon the surface of a piece of wood previously cut to the required shape, and then to apply a blunt steel tool, burnisher, or die to all those parts of the pattern which are intended to be in relief, so as to form depressions in the surface of a depth equal to their required prominence. In doing this, care must be taken, by the very cautious driving of the instruments, to avoid breaking the grain of the wood. The whole is then to be planed or filed down to a uniform surface, after which the wood is steeped in hot or cold water; by the action of this water the parts previously depressed will rise to their former height, and consequently form an embossed pattern which may be finished by the ordinary operations of the carver. A more recent process, to which the name of *Xyloplastic* is given, consists in pressing soft wood into iron moulds, from which it receives a permanent and sharp impression in bas-relief; the wood is softened by steam, and is imbued with certain ingredients to give it ductility.

Very beautiful ornaments of embossed leather, available in lieu of carving for architectural decoration, medallions, picture frames, cabinet-work, and similar purposes, are produced by a process patented by M. Claude Schroth. The dies are made of type-metal, or of the fusible alloy with bismuth, called D'Arcet's. The leather is beaten soft in water, then wrung, pressed, rolled, and fulled as it were, by working it with the hands till it becomes thicker and quite supple. In this state it is laid on the mould, and forced into all the cavities by means of a wooden, bone, or copper tool. In other cases the embossing is performed by the force of a press. The leather, when it has become dry, is easily taken off the mould, however deeply it may be inserted into its crevices, by virtue of its elasticity. The elasticity which thus enables the leather to be removed from an undercut mould is also important as a means of preserving the ornaments from injury by fracture. Remarkable delicacy and sharpness characterise the ornaments thus formed, which may be produced at a moderate expense; while, from the nature of the material, they are little liable to injury. See further on this subject under Leather.

A beautiful process of embossing has been invented by Mr. Edwin Hill, for the production of the coloured medallions impressed on some of the many varieties of envelopes. The colouring and the stamping are both effected by the same machine. The envelope, whether made by hand or machine, is placed upon a small iron table or bed, adjusted to the right position by guide pieces. The stamp or die is at the same time receiving a coating of ink; which, applied only to the *raised* parts of the die, will affect only the *sunk* part of the impression. The die descends, makes the impression, and rises again. One attendant is constantly employed in placing the envelopes for stamping, and another in removing them when stamped. These movements take place sixty times in a minute. The die coats itself with ink or colour by means of composition rollers and an inking-table, somewhat in the same way as a printing-machine. The same machine, or one similar in principle, is applicable to the embossing of paper wafer-medallions. The envelope-embossing apparatus is nationally very important, for each stamped envelope becomes at once a species of paper-money, exchangeable at many times the actual cost of manufacture. The embossing is on this account conducted at Somerset House, by government officers.

EMBRACERY, an attempt to influence or corrupt a jury, or induce them to favour one of the parties in a cause. It is punished by fine and imprisonment. The crime of embracery is completed whether the jury on whom the attempt is made give any verdict or not, or whether the verdict given be true or false.

EMBRASURE (in Architecture) is the indent of a battlement. [Battlement.] It is sometimes used, also, for the splay of a door or window. In walls of some thickness the apertures are splayed on the inside or outside, or both, in order to admit more light, thus making the angles of the wall obtuse instead of rectangular: thus—



A A are splays forming the embrasure. The term is derived from the French.

EMBRASURE (in Fortification) is the opening made in the epaulment or parapet of a battery or fortress, to allow a gun to be fired through it. The part of the interior slope of the parapet immediately below the embrasure is termed the *genouillère*, and its height is of course determined by the height of the carriage of the gun; for field-guns it is therefore 3 feet 6 inches, and also for siege-guns on travelling carriages, while for guns on standing carriages it is only 2 feet 4 inches. The embrasures may be either cut out of a parapet after it is made, or the openings left when the parapet is being constructed; in either case the height of the *sill* or *sole* of the embrasure should not be much more than 4 feet below the crest of the parapet, otherwise the cheeks or sides of the embrasure, being very high, the concussion of the air from the explosion of the gun is sure to cause them to fall in. If therefore, the parapet be more than 8 feet high, it is better to raise the terreplein of the gun. In laying out an embrasure, the usual rule—namely, that given by Sir Charles Pasley—has been to make the neck or interior of the opening 2 feet wide for guns and 2 feet 6 inches for howitzers; and the embrasure being funnel-shaped, with its greatest opening to the front, the inclination of the cheeks to one another is determined by making them widen out 6 inches at the distance of 5 feet; that is, the centre line, or line of fire, being laid down, the bottom of each cheek is made 1 foot from this line at the neck and 1 foot 6 inches from it at 5 feet to the front. This opening of 2 feet for the neck of the embrasure was found too small for the heavy guns and continuous firing used at the siege of Sebastopol, where they were increased as follows: for

Heavy 32-pounders	to	2	feet	6	inches
8-inch guns	„	2	„	9	„
10-inch guns	„	3	„	0	„
Lancaster guns and 68-pounders .	„	3	„	3	„

They should, however, be as small as possible, to afford protection to the gunners.

The cheeks of the embrasure are made almost perpendicular at the neck where the effects of the explosion are slight, and gradually sloping outwards to the front, in order that they may be the better able to withstand this effect: they are, in fact, what is termed in mechanics "in winding,"—that is, not in the same plane. They are revetted according to circumstances with timber and planking, fascines, or gabions,—the former being perhaps the best and the latter the worst description of revetment, though from its being the most accessible the most ordinarily used. Four or five gabions are placed in each cheek; though at Sebastopol eight and nine gabions were required in a parapet 24 feet thick at top (a great thickness, necessitated by the heavy guns, 56- and 68-pounders, of the besieged), in consequence of the looseness of the soil, which, where not retained by some revetment, soon fell in and choked the embrasure. The gabions were again covered with raw hides, hurdles, &c., to protect them from the effect of rapid fire. The Russians in many instances used the large iron ships' tanks taken from the dockyard to revett their embrasures. Embrasures are occasionally revetted with sand-bags, which, unless protected by raw hides, are soon burnt by the flame from the muzzle of the gun. Sandbags are, however, very useful to stuff the gabion revetement of an embrasure with, instead of filling them with earth, which is liable to be shaken out by firing. The sole of the embrasure is, for direct firing, made sloping slightly downwards to the front; but for ricochet firing, where the guns are always fired at a considerable angle of elevation, they are made countersloping.

EMBROCATION (from ἐμβροχή), a moistening, a term employed to denote external applications, which had for their object to soften and dissipate swellings: in this sense they do not differ from fomentations; but the word has been extended beyond its original meaning, and signifies oleaginous or spirituous compounds, which may excite the vessels of the skin to increased action, and produce all the effects of counter-irritants, or by their influence on the extremities of the nerves may assist in resolving spasm, and so act as antispasmodics.

EMBROIDERING AND SEWING-MACHINES. The word embroidery, as employed in the writings of the ancient historians, has reference to all kinds of ornamental work done with the needle; thus comprehending within its meaning every description of decorative needlework, including tapestry and some descriptions of weaving. At the present day, however, the application of the term is much more limited, relating to one kind of needlework only, which, nevertheless, embraces great variety, both as to the materials employed and the mode of using them. The recent invention and amazing extension of *sewing-machines* give a new scope to the term; seeing that the embroidering machines and sewing-machines are so nearly alike in principle, that they had better be described together. It will be convenient, therefore, to treat the subject here under the sub-headings,—Hand embroidery, Embroidering Machines, and Sewing Machines.

Hand-embroidery.—Some of the modes of hand-embroidery partake of the nature of TAPESTRY; but there is one method, in which a very rich effect is produced by inserting pieces of cotton wool, or slips of parchment cut to suit the devices, between the fabric upon which the embroidery is executed and the threads of silk or other material of which the pattern is formed, so that the embroidery may be raised considerably above the surface. Gold and silver thread are often used in embroidery with good effect, and spangles or tinsel are occasionally mixed with the needle-work. The fabric to be embroidered is usually stretched in a kind of frame or loom, and the pattern is drawn either upon its surface, or, if it be very transparent, upon a piece of paper applied underneath it.

The Orientals have always paid more attention to this art than Europeans. The Hebrews had elaborate embroideries in their tabernacle and on their priests' vestments. The Egyptians embroidered their linen garments, and the linen-wrappers of their mummies. The Greeks, the Sidonians, and the Phrygians, were all skilled in this art. The Peruvians, too, when discovered by the Spaniards, astonished them by their elaborate embroideries of gold and silver on feathers. In the embroidery of the middle ages, priests' vestments, hangings, veils, canopies, curtains, door-screens, and corridor-linings, were all operated upon by the needle; noble ladies and their hand-maidens produced the specimens for domestic use; while nuns produced the chief portions for ecclesiastical and sacerdotal adornment. There were three modes practised in those days:—the *low* embroidery, in which the threads were laid flat on the groundwork; the *raised*, in which the figures were in relief, and rounded by means of wool, cotton, parchment, or paper placed beneath the thread; and *gimped*, in which the figures were formed by cords of gold, silver, or silk, and pieces of velvet, satin, silk, or gold. The finest modern examples of hand-embroidery are those produced by the Chinese, Turks, Hindoos, and Persians; some of these workers will put as many as 700 stitches in a square inch.

Embroidery, as a handicraft employment, is in our day singularly affected by changes of fashion. About the year 1846, embroidered dress-pieces for ladies came into vogue; and in a short time there was employment for 2000 hand-embroiderers in London alone, and many thousands in Scotland and Ireland. A pattern was printed in outline on the merino or other material; the stuff was then distributed by travelling agents; and after the embroiderers had worked it, the agents re-collected it. Such dresses are now (1859) nearly out of fashion, and embroidery (as a regular branch of trade) is chiefly applied to window-curtains, table-covers, valences, borderings, and other furniture fabrics. The sewed-muslin work, sent out by Glasgow manufacturers to the Scotch and Irish peasantry, has sent to those countries a certain facility in doing embroidery work whenever the fashion tends in that direction

At the Paris Exhibition, in 1855, several machines were shown, much used in France for pricking or piercing the lines of embroidery, to enable the embroiderers to transfer these lines to the cloth by rubbing coloured powder through the holes. This pricking, which is a very tedious process when performed by hand, is effected by the machines with great rapidity and precision. A jointed frame carries a needle, which vibrates vertically by means of a treadle and connecting cords passing over pulleys. The pointer or pricker, when guided over the traced lines of the design, will make as many as seventy or eighty holes in an inch.

Mr. Hope, in 1855, patented a method of producing effects somewhat resembling what is called *appliqué* work: not by actual embroidery, but by printing patterns on the textile material, either by block-printing alone, or by block-printing combined with embossing. The pattern produced is subsequently finished at pleasure by the needle. Any tint or shade of colour may be used, different from that of the textile material. Surface-printing will suit in some instances, but block-printing is better, seeing that it causes the colouring material to enter more durably into the fibres.

What is now called *Berlin Work*, though not exactly embroidery, may be briefly touched on here. Miss Lambert, in her 'Handbook of Needlework,' gives some interesting details concerning its origin. The kind of work itself is, of course, old enough; the only novelty consists in the care bestowed on the production of patterns. About the year 1805, a Mr. Phillipson published some patterns, which, being badly executed and devoid of taste, did not meet with encouragement. In 1810, Madame Wittich, a lady of great taste and an accomplished needlewoman, justly appreciating the advantages which the art would derive from the production of better patterns, prevailed upon her husband, a print-seller of note at Berlin, to undertake the publication of a series of designs. He did so; and the designs were got up in so superior a manner, that many of the first patterns which were issued from his establishment have had a continued demand almost to the present time. The designer and engraver of these designs are paid as *artists*, in proportion to their talents. The cost of the first coloured design on point paper (divided into small squares) varies from three to thirty or forty guineas; but in some instances, such as the large patterns of Bolton Abbey, Boccaccio's Garden, &c., it is considerably more. The colouring affords employment for men, women, and children. A dozen or so of copies are given to each person at a time, with the original design as a guide. The earnings are from sixpence to three shillings a day, according to the age and skill of the persons employed. Berlin workers have had their work facilitated by an ingenious frame, registered by Mr. Lisle. From a flat horizontal stand rise two pillars, which support the frame somewhat in the same way as a toilet looking-glass is supported, so that the frame may be placed and secured in any convenient position. The canvas or other woven material is wound on rollers, which turn easily on their axes; all the canvas is wound on one roller in the first instance, and is unwound to the other roller as fast as the work proceeds; the space between the two rollers being occupied by a smooth well-stretched portion of the canvas. The rollers are worked by small handles, and there are crotchet-wheels to prevent them from slipping backwards. The side or selvage edges of the canvas are kept stretched by two rods. By this apparatus the Berlin worker or embroidress can work on a piece of canvas of almost any length.

In reference to the designs for patterns in hand embroidery, Mr. Wallis, in a paper drawn up in 1856, said: "In embroidery, the ultra-naturalesque forms which prevailed some six or seven years ago are giving way to a class of designs more suited to production by the needle. Much of this is doubtless to be attributed to the severe character of the ecclesiastical embroidery, for which there has more recently been so large a demand."

Embroidering Machines.—Although embroidery has, until within a few years, been a purely handicraft employment, chiefly cultivated by females as a tasteful and elegant occupation or amusement, it has also assumed the character of a manufacture, a most ingenious machine for executing it having been invented by M. Heilmann, of Mühlhausen. This admirable contrivance, which enables a female to embroider any design with 80 or 140 needles as accurately and expeditiously as she formerly could with one, requires the labour of one grown person to superintend the work, and of two children to change the needles when their threads are used, and to watch continually for any irregularities of action which may need attention. The chief parts of the machine may briefly be described as follows: The needles, which are pointed at both ends, and have their eyes in the middle, so that they need not be turned round between each time of passing through the web, are passed backwards and forwards by the action of small pincers, of which there are two pair to each needle, one on each side of the web, each pair being alternately employed in pushing and pulling the needle through the web. As soon as the needles have passed completely through in either direction, a kind of carriage or framing, which carries the series of pincers by which they have been drawn through, begins to move along a railway so as to draw the needles to the full length of their threads; after which the carriage returns to its original position, and its pincers put the needles again through the web, to be received on the opposite side by the other set of pincers, which then retire with them in like manner. So far as the action of this part of the machine can affect the matter, the needles would continually pass through the same holes in the web; but to enable them to pass through it at different points in succession, according to the pattern required, the web itself, which is placed vertically in a frame furnished with rollers on which it can be wrapped as on the roller of a loom, is caused to assume a different position after each passage of the needles. This is done by connecting the frame with a kind of pantograph, the point or tracer of which can be moved at pleasure over every portion of a drawing or pattern, which represents, on a greatly enlarged scale, the flower or device to be embroidered. The operator brings the point of the pantograph successively to every point of the pattern device at which it is desired to plant a stitch; and by this means so moves the web-frame that the corresponding point of every flower, or place where a flower is to be worked, upon it, is brought opposite to the point of one of the needles. The mechanism by which the pincers are worked is then brought into action by means of handles and pedals, by which every needle of the series is put through the web, and drawn until its thread is brought home; after which the needles return to their original position, while by the working of the pantograph another point, or rather series of points, of the web is brought opposite to them ready for the return stitch. By such means every needle of the series produces a distinct and separate copy, on a small scale, of the pattern, the arrangement of the stitches being precisely according to the movements of the pantograph.

This very ingenious machine was sold by M. Heilmann to Messrs. Köchlin, of Muhlhausen, who patented it in England. All the English rights were afterwards purchased by Mr. H. Houldsworth, the eminent silk-manufacturer of Manchester; he greatly improved the machine, and made an arrangement with Messrs. Schwabe for the joint use of the patent. In its present and most improved form, the machine consists essentially of four parts—an embroidering frame, on which the cloth to be embroidered is stretched; a pantograph attached to the frame; a series of needles and pincers; and mechanism for passing and re-passing the thread through the fabric. The cloth is stretched vertically. The design is sketched on stout paper or on tin-plate, usually six times the size of the work to be done. The pantograph conveys the design, as it were, from the drawing to the cloth. The length of all the stitches is arranged to a definite scale; a hole is punched in the paper at each end of every stitch; the pointer of the pantograph is moved backwards and forwards over the system of holes, thrusting into each hole in turn; and with each movement the needles are drawn backwards and forwards though the cloth. The action of the needles, although improved like everything else belonging to the machine, may be understood from the description given in the last paragraph. Some of the machines are large enough to employ six persons; some are small enough to be worked by one. Very little hand-work is necessary in finishing embroidery worked by these machines. There are certain limits, beyond which, machine-embroidery is not so useful as that effected by hand; but it has this merit, that the embroidering is equally good on both sides of the cloth. Mr. Houldsworth has invented a mode of embroidering in curves; he stretches the fabric on elastic cross-pieces; screws it up so as to draw the threads into a curved line; embroiders in a *straight* line; loosens the screws; and allows the cloth to resume its original position—the rows of embroidery stitches then appear in curved lines instead of straight. In producing a chintz-like effect, many colours are used in many needles. Another mode of producing variegated effects is to dye the silk thread differently at different parts of its length.

Attention has been drawn by Mr. Wallis to two circumstances affecting in an important degree the use of embroidering machines; namely, their limited scope for elaborate work; and their influence on artistic design. On the first point he says: "In variety of effect the embroidering machine can never compete with hand-embroidery; and although, as in the dress embroidered for her Majesty by the late Mr. Louis Schwabe of Manchester, the effects of the original drawing are given in all their variety, this has only been effected at a great sacrifice of all the economical powers of the machine. When Mr. Schwabe first showed me this specimen in 1844, he said, 'I am written to, and asked if my machine would execute the design? I replied, that any design which her Majesty wished executed should be produced by it. When the drawing came, I saw the mistake I had made; but resolved, cost what it might, that the work should be done—and there it is.' As an illustration of what can be done by the embroidering machine, the example is interesting; but as an illustration of its economical use, or its superiority over hand-embroidery, it is worthless." On the other point, Mr. Wallis remarks: "Silk at 40*s.* a pound is too costly to be wasted; therefore, it is desirable that each needleful should do its work, and that no fragments should remain to be cut away at a loss. Hence patterns have to be designed to the needleful. If a pattern, however excellent in the abstract it may be, consumed one needleful of 36 inches out of two needlefuls of 42 inches each, it would be considered anything but sound economy in machine-embroidering to execute it, as 8 (6?) inches would be lost for each needle employed—a waste, upon any extent of production, which would astonish those who are not in the habit of thinking about mere fragments in the materials of manufacture. It will at once be seen from this fact, that the design for machine-embroidery must ever be somewhat peculiar, and to a certain extent limited in range of form; and that all the most successful—certainly the most economical—are made almost in the presence of the machine by which they are to be executed, and for the most part under no higher inspiration than that of a species of artistic measure-table: such as 'two needlefuls make one flower; three flowers make one repeat; twenty repeats make one border; four borders make one table-cover decoration.' One can thus tell, almost to an inch, certainly to a yard, how much silk will be consumed in a given operation."

Sewing Machines.—We must now pay attention to those machines which perform the operations of sewing and stitching, instead of that of embroidery.

It is evident, on a slight consideration, that the principle of these machines is nearly identical, however dissimilar may appear the mode of working. In both, there are needles threaded with cotton, silk, or other material; and in both, the needles pass to and fro, from one surface to the other of the piece of cloth, leaving tightened convolutions of thread to mark their passage. The two chief points of difference are, that the needles are more fixed in position in the sewing than in the embroidering machines; and that the object in view is rather to fasten and strengthen than to decorate. To describe the numerous patented sewing-machines in detail would be both tedious and unnecessary; a few words relating to Newton and Wilson's Boudoir Sewing-Machine will suffice, as giving one particular type of a large class. This machine is constructed chiefly for domestic sewing, and for light manufactures. It is mounted on a portable table; under the table is a treadle acting on a small friction-wheel, which drives two small levers, one above and one below the bottom of the machine. The upper lever carries a *piercing needle*, and at the same time feeds the machine with its work, carries it forward, and regulates the length of the stitches. The under lever carries a *looping needle*, for completing and securing the stitch on the under side of the cloth. This looping needle, or looper, is a hook, which takes hold of the loop of thread after it has been passed through by the piercing needle, and retains it till this last-named needle, passing again through the cloth, enters this loop and leaves another, drawing the first loop tight in its receding motion. The stitch thus made is what embroiderers call the *tambour-stitch.* Instead of this a different stitch is formed, by using a looper which has a hook with a longer point, with an eye formed to carry a second thread; the needle and this looper, by alternately intercepting the threads they respectively carry, form an interlaced or *chain-stitch* on the under side of the piece of cloth; while both together form a *back-stitch* on the upper surface. This machine can turn down, fold, hem, and lay on and fix binding, as well as perform sewing and stitching.

A few figures were given in the 'Mechanics' Magazine,' about the middle of the year 1859, showing to how astonishing a degree the use of sewing-machines has extended. The following appeared as the result of inquiries made in England, and in the United States:—

	Great Britain.	United States.
No. of patents granted . . .	200	300
Manufacturers	5	25
Kinds of sewing-machines . . .	6	30
Kinds of lock-stitch machines . .	3	10
Machines sold weekly . . .	100	1500
Prices	3*l.* to 30*l.*	1*l.* to 30*l.*
Lowest prices for lock-stitch machine	11*l.*	10*l.*
Whole No. in all	10,000	100,000

Some of the English patents (dated before 1852) do not extend to Scotland or Ireland, and American sewing-machines are largely employed in those two portions of the United Kingdom; but in England and Wales the American machines are virtually shut out.

In both England and America the use of the machine is largely extending. The shirts, collars, and mens' clothing sold in the London shops, are in considerable part either stitched or sewn by machines. Army clothing is begining to be sewn in the same manner, especially in Ireland, where the cheaper American machines may be employed. Mr. Peter Tait, of Limerick, in evidence given before the Contracts' Committee of 1858, stated that he cuts out army clothing by steam-power, and effects much of the sewing by machines worked also by steam-power; he can make 4000 suits of Infantry clothing per week, if needed; and employs several hundred men in the finishing operations, none at less than a guinea a week. In America, Cincinnati is the great clothing town for the Western and Central States. The articles are cut out in large warehouses, then given out by contract to master-tailors, who employ hands by the day or by the piece; sewing-machines are very largely employed in the making up, each doing as much work as ten hand sewers. In 1851, there were 108 establishments employing 10,000 hands; and in the next eight years there was a large increase. The owners of most of the establishments are German Jews, and the workmen Germans.

EMERSION (Astronomy), the reappearance of one heavenly body from behind another after an eclipse or occultation.

EMERY; EMERY PAPER. In the NATURAL HISTORY DIVISION, under ADAMANTINE SPAR and CORUNDUM, a brief notice is given of the mineralogical structure and constituents of emery. We shall here add a few details concerning the manufacture and trade, of recent date.

Dr. Lawrence Smith, an American geologist, made the discovery of a deposit of emery while residing at Smyrna in 1847. On reporting his discovery to the Turkish government, a commission of inquiry was instituted, and the subject soon acquired mercantile importance. Arrangements were made with a mercantile house at Smyrna, leading to an increased sale and a diminished price of Turkey emery. The mining of the emery is of the simplest character in the vicinity of Smyrna. It is rarely necessary to explore the rock in which the lumps of this mineral are found; for a certain redness of colour in the earth immediately surrounding each lump nearly always indicates the exact locality of the emery. Sometimes, before beginning to excavate, the spots are sounded by means of an iron rod with a steel point, and when any resistance is met with the rod is rubbed in contact with the resisting body: the effect produced on the rod enables a practised eye to decide whether it indicates emery or not. The smaller blocks are carried away first in the state as obtained. The larger blocks are broken by hammers; or, if this does not suffice, they are subjected to the action of fire for several hours, and on cooling they easily yield to blows. It occasionally happens that large masses are abandoned from the impossibility of breaking them into pieces of convenient size, seeing that the mode of transportation, either on canals or horses, requires that pieces shall not exceed 100 lbs. in weight each.

When the blocks of emery have been conveyed to the manufactory, they are broken up by hammers into pieces nearly similar in size to the stones for macadamising roads. These pieces are then reduced to coarse powder, either by rollers or by stampers, driven by water or steam power. The coarse powder is next sifted through cylindrical wire-cloth sieves, the cloth having from 16 to 90 wires to an inch-degree of fineness in the wire-cloth gives name to the different qualities of emery produced. No. 16 sieve gives emery about the size of mustard-seed; engineers sometimes require fragments nearly as coarse as pepper-corns; the kind numbered 90 is very fine; and some for special purposes, as high as 120, is sifted through lawn-sieves. The finest obtainable is that which floats in the atmosphere of the stamping-room, and is deposited on the beams and shelves, from which it is occasionally collected. When reduced to a powder, emery varies in shade from dark gray to black; but the colour affords little or no indication of its commercial value. The chemical and mineralogical constituents are noticed in the NATURAL HISTORY DIVISION, and need not engage attention here.

The manufacturers who prepare emery for the market seldom wash it; this is done by the purchasers, glass-makers and others, who require a greater degree of precision than can be obtained by sifting. The manufacturers of plate-glass, who require large quantities, sometimes adopt the following plan: Twelve or more copper cylinders are prepared all alike about 2 feet in height, but of different diameters, the smallest 3 inches and the largest 40. They are placed on a level, in a row; there are small troughs or channels of communication at their upper edges, and the largest has a waste-pipe near the top. In beginning the process, all the vessels are filled with clean water. The pulverised emery, churned up with abundance of water in another vessel, is allowed to run into the smallest cylinder through a tube opposite the trough leading to the second cylinder. During this short passage the water deposits such of its coarsest emery as will not bear suspension even for that limited time; flowing onward, it deposits particles a little finer in the next cylinder; and so on throughout the whole series. Eventually the water forms a very languid eddy in the largest cylinder, and deposits therein all the remaining particles. If there are twelve cylinders, emery powder of twelve different degrees of fineness is then obtained. The powder, when the water has been drained off, is carefully dried for use.

Emery is employed in various ways in manufactures. *Emery powder* is applied to the grinding of glass and the polishing of metals and numerous other substances, sometimes dry, and at other times moistened with oil or with water. *Emery paper* consists of a thin layer of the powder cemented to a sheet of paper by means of glue. There are six or seven degrees of fineness, depending on the meshes of the sieve employed in sifting. Emery paper is either used by the hand, or it is wrapped round a slip of wood to act like a file; if moistened with oil, it cuts more smoothly, but leaves the surface more dull. *Emery cloth* differs from emery paper only in the use of thin cotton cloth instead of paper as a foundation for the powder; it is less useful to engineers and other artisans, as being too flexible, but it is preferable for many household purposes. *Emery sticks* are carefully formed slips of wood with a layer of the powder glued on their surface; the sticks are from 8 to 12 inches long, and may vary in section as much as files. For engineering processes, or metal work generally, they constitute a mode of employing the powder more economical than emery paper. *Emery cake* consists of a mixture of bees'-wax with emery powder, carefully made by heating, stirring, kneading, and rolling. It is employed for dressing the edges of polishing-wheels in cutlery and other manufactures. It is sometimes applied to the wheel while revolving, but more usually when stationary. *Strop paper* consists of a peculiar mixture of emery, glass, and paper pulp, made into sheets, and pasted or glued to the surface of a flat piece of wood, to be employed as a razor-strop when slightly rubbed with oil: the emery and glass together constitute more than half the weight of the prepared paper. *Emery wheels* are made of a composition of coarse emery powder with pulverised Stourbridge clay, moistened to a thin paste with water, and pressed into shape by means of a metallic mould. After being dried and baked it forms a sort of artificial emery stone, which cuts very quickly and yet wears away slowly. It is employed in the form of wheels, discs, or laps, suitable for grinding, cutting, and polishing glass, enamels, metals, and other hard substances. *Emery stone* is sometimes made of flour-emery alone, forced into and shaped by a metal mould, without the addition of any clay, and then baked. It will produce a very smooth surface, but not a high polish. *Waterproof emery cloth* or *paper* is prepared by coating the material on both surfaces with a mixture of boiled linseed oil, African copal, Venice turpentine, Venetian red, Prussian blue, and litharge, and then sifting pounded emery on one or both of the moistened surfaces.

EME'TICS (ἐμετικὰ) are substances which influence the stomach in a peculiar manner, so as to invert its action and cause vomiting; and this effect is produced without reference to the quantity of matter introduced into that organ or into the circulation. This definition is intended to exclude, on the one hand, the mere inversion of the stomach by the introduction of food or drink, either in inordinate quantity, or of too stimulating a quality; and, on the other, to comprise those means of causing vomiting by their direct introduction into the circulation by injection into a vein. The action of emetics must be viewed in two stages, the primary and secondary. The primary effects of emetics are limited to the emptying of the stomach, compressing, during the act of vomiting, the gall-bladder and pancreas, and exciting to contraction the muscular parieties of the abdomen and thorax, as the machinery by which the process of vomiting is chiefly accomplished. We shall here briefly trace the obvious phenomena of this process, without attempting to account for their occurrence.

Soon after a quantity of an emetic substance or solution (such as ipecacuanha or emetic tartar) has been received into the stomach, a feeling of anxiety is experienced in the epigastrum, a general uneasiness termed nausea is felt, which progressively becomes greater, till it ends in the forcible expulsion of the contents of the stomach. This gives a succussion to the whole frame, every part of which experiences more or less of a vibratory motion. The condition of the system is considerably different prior to and during the act of vomiting. In the preliminary stage, the countenance is pale and collapsed; the pulse is small, contracted, irregular, but quick more generally than slow; chilliness is felt, and a cold perspiration may ooze from the surface, all which symptoms disappear when the expulsive movement takes place. Then the face appears flushed; the pulse becomes quicker, fuller, and stronger, and rarely subsides till some time after all vomiting has ceased. If, after a brief interval, the expulsive action be not renewed, a state of langour succeeds, with tendency to sleep, and generally a considerable flow of warm perspiration.

Such are the effects of an emetic, when given in a dose sufficient to produce vomiting; but, if given in a smaller quantity, and repeated at intervals, it will merely create a state of nausea, during which the appetite is lowered, and arterial action is much diminished, while the function of absorption is roused to great activity.

The secondary effects of emetics depend upon the succussion of the frame, the equalisation of the circulation, the increased secretion from the mucous membrane of the stomach, and also of the duodenum as well as the liver and pancreas, and frequently from the skin.

The secondary effects of nauseating doses are diminished arterial action and augmented absorption.

We shall now state a few of the morbid conditions to which these agents are suited, and a few of those for which they are unfit.

In fever. Whatever opinions may be entertained respecting the nature and origin of fever, there can be no question but that the sanguiferous system powerfully feels and shows disturbance, and in no point more conspicuously than in the capillaries. These become the seat of those morbid actions, to counteract which is the chief aim of the early treatment. By these vessels, too, are executed the functions of secretion, deposition of the nutrient material, exhalation, and, in some degree, the evolution of animal heat. The consequences of deranged action of the capillaries are—diminished or vitiated secretion, suspended nutrition, altered exhalation, and the animal heat augmented or diminished, or unequally diffused. But while the diseased impression is confined to the general circulation, which it always is for some time (varying in different cases and constitutions), the series of morbid actions may be arrested by venesection, purgatives, or more certainly by an emetic. This should be administered at as early a period of the disease as possible; but even should it fail in cutting short the febrile movement, still it clears the stomach, and fits it to retain whatever may subsequently be had recourse to in order to moderate or regulate the future condition of the system. Emetics invariably render the disease milder, owing to the greater freedom of the secretions which follows their use; and they may be advantageously repeated even in the more advanced stage, frequently inducing sleep and a moist state of the skin. They may be employed in epidemic, typhus, common fever, and exanthematous fevers, especially measles, scarlet fever, and small-pox. For the slight febrile affections of children, generally caused by something offending the stomach, nothing is so well suited or so efficacious as a gentle emetic. In bilious fevers emetics are required, especially at the beginning. In intermittent fevers, if given before the paroxysm, they early bring on the sweating stage, thus concentrating the fit into a short period. Their tendency to produce perspiration often renders them useful in rheumatic fevers. In common inflammation of the throat, and still more so in croup, emetics are of decided utility. In common catarrh they frequently shorten the disease; and in the suffocative catarrh and catarrh of old age, emetics mechanically unload the lungs, and render the respiration freer. Dr. James Clark and Dr. Carswell even think that they can dislodge tubercular matter from the lungs in the early stages of consumption. (See Clark 'On Consumption.')

Few agents are more useful in whooping-cough than emetics; and in many cases of indigestion, especially if accompanied with sick headache or hypochondriasis, emetics give effectual relief.

Emetics are very improper where there is a disposition to apoplexy, or tendency of blood to the head, or where the patient is liable to hæmorrhage from any organ, or is subject to hernia. They are also to be avoided during pregnancy.

Emetics are often resorted to when any poisonous substance has been taken. For this purpose a scruple of sulphate of zinc in a tumbler of warm water is proper, or a table-spoonful of common mustard in a tumbler of water. But when opium, belladonna, or other narcotic poison has been taken, emetics rarely act. The stomach-pump should then be used.

EMETINE, *Emeta, Emetia,* a vegetable alkaloid obtained from ipecacuanha-root, and in which the powers of that medicine reside. In order to prepare it, the root is reduced to powder, and then treated with sulphuric ether to separate a fatty substance, and afterwards with boiling alcohol. The alcoholic solutions, when evaporated, leave a bitter brown extract, which contains emetine combined with gallic acid. This is to be redissolved in water, and boiled with an excess of magnesia, which decomposes the gallate of emetine; the magnesian precipitate is to be washed with a little cold water, and then boiled in alcohol. The emetine dissolved in the alcohol is separated by evaporation; but as it is coloured, it is recombined with an acid, and after being decolourised by animal charcoal, it is to be again precipitated by magnesia.

Emetine, when pure, is white, pulverulent, and uncrystallisable; its taste is rather bitter; it melts at 104° Fahr., and afterwards decomposes at a temperature below 212°. It suffers no change by exposure to the air; it is slightly soluble in cold water, but readily dissolved by alcohol; the solution restores the blue colour of litmus paper which has been reddened; it is precipitated by tincture of galls; acids are but imperfectly saturated by it, and it yields with them uncrystallisable salts, which have been but little examined. The gallotannate is neither emetic nor poisonous.

In the dose of half a grain emetine is stated to act as a powerful emetic, and in larger doses its effects are extremely violent.

It is composed of—

Hydrogen	7·77
Carbon	64·57
Oxygen	22·95
Azote	4·30
	99·59

EMIGRATION, may be defined to be a man's leaving his native country with all his property to settle permanently in another. Emigration is therefore necessarily implied in the word colonisation, and it is by the terms of our definition easily distinguished from a man's temporary absence from his native country and from the kind of absence specially called absenteeism.

Though a man may be properly called an emigrant who leaves Great Britain or Ireland, for instance, and settles in France or Germany or elsewhere in Europe, the term has in modern times come to have a more restricted and particular sense. By the term emigrant we generally understand one who leaves an old and thickly peopled country to settle in a country where there is abundance of land that has never been cultivated before, and where the native population is thinly scattered, and the foreign settlers are yet either few compared with the surface, or none at all. The countries to which emigration is mainly directed at present are the British possessions in North America, the United States of North America, the great island of Australia with Van Diemen's Land, New Zealand, and the Cape of Good Hope.

An emigrant to any of these remote countries must be either a capitalist or a labourer. An emigrant may combine in himself both conditions; for even a mere labourer cannot emigrate without some capital, though the amount may be only enough to convey him to the spot where his labour and skill will be in demand. It was long a prevalent notion that emigration should be discouraged or prevented, as tending to weaken a nation. The objection, we believe, was generally founded rather on a notion that the nation lost by its diminished population, than that it suffered from the abstraction of capital. As to the matter of population, however, some observers even then could not fail to remark, that emigration did not seem to diminish the population, but that on the contrary it seemed to be soon followed by an increase. This was observed with respect to Portugal at the time when she was extending her conquests and colonies, and is a fact confirmed by more recent experience, the explanation of which presents no difficulty. The abstraction of capital, skill, and industry might seem, and indeed is primarily, so much good taken from the mother country; but inasmuch as the emigrants retain in their new settlements, through the medium of commercial exchange which is daily becoming more rapid and easy, a connection with the parent state, it may be and often is the fact, that they ultimately contribute more to the wealth of the mother country when in the new settlements than they could have done at home. Many of those, for example, who settle in the western States of America or in Canada with no capital beyond their hands, by their industry become the possessors of a well-cultivated piece of land, and ultimately consume more of the products of British industry, for which they must give something in exchange, than if they had remained in their native country. And as, in order that emigration to new countries may be a successful undertaking to those who emigrate, and ultimately advantageous to the mother country, there must be an emigration both of capitalists and labourers, it would seem to follow that a state, if it consult the happiness of its citizens, should place no impediments to the emigration either of capitalists of all kinds or of labourers or artizans of any kind, but should on the contrary give reasonable facilities.

If a state then should be wise enough not to discourage emigration, it may be asked, should it aid and direct it? So far as a state should aid and direct emigration, there must be two distinct objects kept in view by the state; one must be to benefit the parent country, the other to benefit those who emigrate. On the contrary, as to the individual who emigrates, whether he emigrates under the protection and direction of the government or not, his object generally is of course to better his own condition.

One cannot well conceive why a state, or any section or part of a nation, should make any contribution or raise any fund for the purpose of aiding emigration, except it be with the view of bettering the condition of some who cannot find employment at home, and at the same time adopting some systematic plan for improving the condition of those who are left behind. Yet any system of emigration thus conducted by government, or by societies, or by the inhabitants of particular districts, would fail in its primary object, relief to the emigrants, unless a corresponding amount of capital should be taken out of the country by other emigrants who might settle in the same place to which the emigrant labourers were sent. To effect such an adjustment between capital and labour, not only should both these elements of wealth in due proportion be transported to the new country, but such proportion should, for some time at least, be maintained by the body which superintends such system of emigration; an arrangement which seems impracticable, except by some such provisions as are hereafter mentioned.

It is further to be observed that as no persons can ever succeed as emigrants who are not sober, intelligent, and industrious, and as such alone are consequently fit people to go to a new country, such alone should be sent out by a state or a society, if it interferes in the matter of emigration. But if a large number of the most industrious labourers should emigrate from a given district, and leave behind them the worthless and idle, though the emigrants might better their condition and improve the settlement of which they go to form a part, the mother country would be no gainer by this change. We are not inclined to consider that any advantage, at all commensurate to the expense, would result from any emigration, however extensive, from districts where there is a superabundant and pauperised, or a pauperised and not superabundant population. If the idle, the ignorant, and the vicious, were exported wholesale, they would only die a few years sooner in the land of their new settlement, without conferring any benefit on it, and those of the same kind who were left behind would hardly be more susceptible of improvement for the absence of any part of their numbers which did not amount to pretty nearly the whole number; while the industrious and the intelligent, who, by the supposition, remain at home and are willing to labour whenever it is in their power, would hardly derive any benefit by this removal of the bad from among them, at all commensurate to the amount of capital which must be expended on such wholesale exportations. Besides, as already observed, unless a proper supply of emigrant capitalists can be secured, all general plans for the emigration of labourers can only lead to disappointment and starvation. Any plan therefore which shall have for its object the amelioration of a population sunk in ignorance or debased by pauperism, must be one of an internal character, one which must gradually and on certain fixed principles aim at removing the evils which exist in the social system. Emigration must be left to the free choice of individuals, and must be recommended to the young, the sober, and industrious solely on the grounds of offering to them a reasonable prospect of bettering their condition in a new country.

The disadvantages of emigration however, when there is no plan, no controlling or directing power, are obvious. Emigrants often go to a new country without any definite or clear notion of what they are going to. Dissatisfied or unhappy at home, imagination pictures to them a remote and unknown country as an asylum from all the evils of life; or if they have any distinct idea of the new kind of existence which they are going to adopt, they often underrate the difficulties of the undertaking, or form a false estimate of their own capabilities to meet them. It is no wonder then that so many, on landing in the New World, are startled at the obstacles which then stare them in the face, and shut their eyes to the real advantages, such as they are, which a fertile unoccupied soil presents to a hardworking industrious man.

Years.	North American Colonies.	United States.	Australian Colonies and New Zealand.	All other Places.	Total.

Average annual emigration from the United Kingdom		
	From 1815 to 1858	109,026
	For the 10 years ending 1858	261,865

* The Customs returns do not record any emigration to Australia during these ten years, but it appears from other sources that there went out in 1821, 320; in 1822, 875; in 1823, 543; in 1824, 780; and in 1825, 458 persons. These numbers have not been included in the totals of this Table.

We have noticed above, that the abstraction of population for the purposes of colonisation appears to promote an increase rather than a diminution in the numbers of the parent state. One of the most remarkable facts in the history of Great Britain is the rapid increase of the population. The positive increase in our own kingdom has been pointed out in the article CENSUS. While the population of France and Germany has increased within the last fifty years in a very small degree; while in Spain, Portugal, and Italy it has probably decreased; Great Britain has increased from 10,800,000, as given in the census of 1801, to 20,900,000 in that of 1851; and in the middle of 1858, the Registrar-General estimated the population of England and Wales alone at 19,523,000: Ireland and Scotland are omitted, as there was no census of 1801. In addition to this increase, swarms have been thrown off to which the ancient migrations from the North are insignificant in their total amount, though the emigration has been less striking from its being not an irruption but a gradual progress. In forty-four years, from 1815 to 1858 inclusive, during which an account of avowed emigrants has been taken, 4,797,166 persons, male and female, have left the shores of the United Kingdom; and these have been enabled to form what may now be termed three mighty empires, subordinate to our own, in Australia, North America, and South Africa; independent of the branch streams which have flown off to Ceylon, the West and East Indies, Guiana, and other British possessions. The United States of America is the only dominion that can afford anything like a parallel, and even that is indebted to us for 2,890,403 persons, who have proceeded thither, the greater proportion of whom have been from Ireland, and chiefly from the years beginning with 1847.

In 1857 the total number of emigrants from the port of Liverpool only, was 155,652; of these 9788 were for the North American colonies; 106,918 for the United States; 32,631 for Australia and New Zealand, and 324 for other places. Of these emigrants England supplied 50,289; Scotland, 8161; Ireland, 71,195; and various foreign countries, chiefly Germany, 6414. The emigration to Australia was principally English; that to the United States principally Irish.

Many emigrants, however, proceed to the North American colonies by New York, and no account is taken of the passage either way on the borders between them and the United States. The population thus exported seems scarcely less fertile than at home. We give the latest returns of the population of these colonies which are mainly occupied by a British population, our youngest and most vigorous:—

In North America:		Males.	Females.	Total.
Canada	Western	499,067	452,937	952,004
	Eastern	449,967	440,294	890,261
New Brunswick		99,526	94,274	193,800
Nova Scotia		137,677	138,440	276,117
Prince Edward's Island and Cape Breton		36,137	35,365	71,502
Newfoundland		52,274	44,232	96,506
Bermuda		4,797	6,295	11,092
Total		1,279,445	1,211,837	2,491,282

The numbers given for Canada are from the census of 1851 for Western, and the official return of 1852 for Eastern Canada; the estimated numbers of both in January 1857 were 2,500,000. For New Brunswick they are taken from the census of 1851, and the official returns of 1853. For Nova Scotia, from the census of 1851. For Prince Edward's Island, the census of 1854; estimated in 1857 at 117,000. All have increased since the returns. For Newfoundland the numbers are taken from the census of 1845, and in 1857 the population was estimated at 125,000. For Bermuda the authority is the official return of 1853.

In Australia:	Males.	Females.	Total.
New South Wales	171,673	133,814	305,487
Victoria	308,983	176,786	485,769
South Australia	55,735	54,182	109,917
Western Australia	9,560	4,733	14,293
Tasmania	45,916	34,886	80,802
New Zealand	29,435	22,720	52,155
" Natives	31,667	24,303	55,970
Total	652,969	441,424	1,104,393

The returns for New South Wales are from the census of 1857; for Victoria, the official return of September 30th, 1858; for South Australia, the official return of December 31st, 1857; for Western Australia, the official return of June 30th, 1858; for Tasmania, the census of March 31st, 1857, which includes 3008 convicts, 16 aborigines, and 690 military and their families; for New Zealand, the official statistics of 1857. On June 30th, 1859, the population of Victoria had increased to 517,366, of whom 330,212 were males, and 187,154 were females; the number of Chinese immigrants at that period was 45,160, all of whom were males.

In Africa the principal point of emigration has been the Cape of

Good Hope and Natal. In these the population, according to the return of 1856, was

		Males.	Females.	Total.
Cape of Good Hope	Western Division	81,347	80,691	162,038
	Eastern Division	52,973	52,085	105,058
Natal		52,045	57,755	109,800
Total		186,365	190,531	376,896

exclusive of 112,988 settled natives in Natal.

In these three divisions of the British colonies, there are now representative governments, the privilege of self taxation, and the right of a free press, in short, a complete reproduction of the British constitution. To other colonies, especially to British Guiana and some of the West India islands, the emigration has been considerable; but as the emigrants become mixed with an older and in some cases a coloured or foreign population, we cannot trace the British element so clearly. We give, however, the population returns of the other British settlements, with the year of the return:—

The total amount of the population of the various settlements of Great Britain by these returns is 7,744,422 persons, of whom 3,890,707 are males, 3,426,765 are females, and 426,950 of whom the sex is not distinguished.

The effect has been so far good, that the inhabitants of the North American and Australian colonies are, with the exception of the United States, among our best customers. It is not remarkable, therefore, that so much attention has been paid of late years to the subject of the transmission of emigrants thither, and of means for enabling them to settle there in comfort. Government, accordingly, has undertaken to a considerable extent the business of regulating emigration. First, an agent-general for emigration was appointed. This officer introduced many judicious plans for rendering the passage of emigrants across the ocean as free as possible from discomfort, and a code of rules was framed to secure this and other objects. The functions of the agent-general for emigration are now exercised by the Land and Emigration Commissioners. Emigrants are also protected by the Passengers Act. The Act 5 & 6 Will. IV. c. 5, passed in 1835, having proved insufficient for the purpose, several amended Acts were passed, of which the latest is the 18 & 19 Vict. c. 119, passed in 1855. Its objects are to regulate the number of passengers in each ship, and to provide for their proper accommodation on board; to ensure a proper supply of provisions and water for their use; to provide for the sea-worthiness of the vessels; to secure a sufficient number of boats in case of accidents; and to protect emigrants from the numerous frauds to which at various stages of their undertaking their helplessness and inexperience expose them. If the ship does not sail on the day mentioned in the agreement, the Passengers' Act compels the captain to victual the emigrants just the same as if the voyage had commenced; and they are entitled to remain on board forty-eight hours after the ship reaches her destination.

As a further protection to emigrants, and to enforce the provisions of the Passengers Act, government emigration agents are appointed for the ports of London, Liverpool, Plymouth, Southampton, Glasgow and Greenock, Dublin, Cork, Belfast, Tralee, Limerick, Waterford, Londonderry, and Galway. These officers act under the immediate directions of the Colonial Land and Emigration Commissioners. They procure and give gratuitously information as to the sailing of ships, and means of accommodation for emigrants; and whenever applied to for that purpose, they see that all agreements between ship-owners, agents, or masters, and intending emigrants, are duly performed. They also see that the provisions of the Passengers Act are strictly complied with; namely, that passenger-vessels are sea-worthy, that they have on board a sufficient supply of provisions, water, medicines, &c., and that they sail with proper punctuality. They attend personally at their offices on every week-day, and afford gratuitously all the assistance in their power to protect intending emigrants against fraud and imposition, and to obtain redress where oppression or injury has been practised on them.

In the colonies there are Government Emigration Agents at the following places:—

Canada.—Quebec, Montreal, Ottawa, Toronto, and Hamilton.

New Brunswick.—St. John's, St. Andrew's, Chatham (Miramichi), Bathurst, Dalhousie, and Richibucto.

Australian Colonies.—Sydney, Queensland (late Moreton Bay), Melbourne, Geelong, Portland Bay, Hobart Town, Launceston, Perth, Fremantle, Adelaide, and Auckland.

Cape of Good Hope.—Cape Town, Port Elizabeth, Simon's Town, and Natal.

And also in Jamaica, Bahamas, British Guiana, Trinidad, Nevis, Sierra Leone, and St. Helena.

The duty of these officers is to afford gratuitously to emigrants every assistance in their power by way of advice and information as to the districts where employment can be obtained most readily, and upon the most advantageous terms, and also as to the best modes of reaching such districts.

The Emigration Commissioners, while they have funds for the purpose, grant passages to New South Wales, Victoria, South Australia, the Cape of Good Hope, and Natal, to persons strictly of the labouring class who may be considered eligible emigrants. The funds are supplied entirely from colonial revenues, and in the administration of them the commissioners act as trustees for the colonies, and are therefore bound to look exclusively to colonial interests. They do not consider, therefore, how distress in this country may be best relieved, but how the largest number of emigrants most suited for the wants of the colony may be procured and sent out. In deciding what classes are most suited to the wants of the colonies, the commissioners are guided by reports and instructions received from time to time from the governments of the respective colonies, either direct or through the secretary of state. The commissioners are occasionally also able to grant passages to Western Australia; but they have no funds for assisting persons wishing to emigrate to the North American colonies.

In British Guiana, the Governor, under Ordinance No. 7, of 1854, sect. 4, is authorised by proclamation to name the places from which emigration on bounties is permitted, and to fix the rates of bounty for the introduction of emigrants, under the age of forty, competent and willing to engage in agricultural labour.

Emigration is one of the "modes of relief" contemplated by the Poor Law Amendment Acts (4 & 5 Will. IV. c. 76; 11 & 12 Vict. c. 110; 12 & 13 Vict. c. 103; and 13 & 14 Vict. c. 101). In some years a large number have emigrated with the assistance of funds obtained under the act, 4 & 5 Will. IV. By sect. 62 of that act, owners and ratepayers are empowered to raise money on security of the rates for the purposes of emigration, under the authority of the Poor Law Commissioners. The sum so raised must not exceed half the average yearly rate of the preceding three years, and it must be repaid within five years. The money is advanced to emigrants by way of loan, and is recoverable against persons above the age of twenty-one, who, having consented to emigrate, refuse to do so after the expenses of emigration have been incurred; and the loan is also recoverable if persons who emigrate shall return to this country. By the 12 & 13 Vict. c. 103, the guardians of any parish or union are empowered to expend money to the amount of 10*l.* upon the emigration of any poor person belonging to the parish or to any parish in the Union, without the necessity of a parochial meeting to give their consent. But the gross amount expended must not exceed the limit fixed above, and a majority of the guardians of the parish of the settlement must express their concurrence in writing in the resolution of the Board of Guardians for such expenditure. This written concurrence must be transmitted, together with a list describing the proposed emigrants, to the Poor Law Board, who are to issue their order to confirm the resolution. The 13 & 14 Vict. c. 101, s. 4, enables Boards of Guardians, under similar restrictions, to expend money in and about the emigration of orphan or deserted children under sixteen having no settlement, or whose settlement is unknown. But it requires that no emigration of any such orphan or deserted child shall take place without the consent of such child given in petty session, and unless a certificate thereof under the hands of two justices shall have been transmitted to the Poor Law Board. Certain conditions are inserted by the Poor

---

* Exclusive of 8704 aliens.

† In Trinidad the estimated population in 1857 was 80,000.

Law Board in all orders sanctioning the emigration of poor persons, of which the most material is, that the party emigrating shall go to some British colony not lying within the tropics; and the guardians are empowered to expend certain specified sums in the conveyance of the emigrant to the port of embarkation, and on the outfit, including bed, bedding, and clothing.

Under the Irish Poor Law Act, money may be raised for enabling poor persons to emigrate to British colonies; but the money so raised must not exceed one shilling in the pound on the net annual value of rateable property.

The Bounty System derives its name from the mode in which the proceeds of land-sales are applied in obtaining immigrants. In this case persons who introduce persons into the colony receive so much per head according to the terms of agreement. The contractors engage to find persons willing to emigrate, and undertake to land them in the colony. This system is in force only in some of the Australian colonies. In New South Wales 51,736 persons were introduced from 1831 to 1842 under bounties.

The mode in which unoccupied land is disposed of in the colonies has a most important influence on the condition and welfare of immigrants. By the application of a general principle of law, the waste lands in the British colonies were considered to be vested in the Crown, and that every private title must rest upon a royal grant as its basis. But since 1831 another principle has been acknowledged and observed: that the crown holds the lands in question for the purposes of the public good, not merely for the existing colonists, but for the people of the Britsh empire collectively. It must be appropriated to the public uses and for the public benefit. The Land Sale Act for the Australian Colonies (5 & 6 Vict. c. 36) prohibits land being alienated by her Majesty, or by any one acting under her authority, except by sale, and in the manner directed by the act.

Down to the year 1831 no regular or uniform system of selling land appears to have been adopted in the British colonies. In place of such system, conditions were attached to the occupation of land under the name of quit-rents, money payments, or the cultivation of the soil; but these conditions were not effectually enforced, and in fact it was generally found impossible to enforce them. Land was profusely granted to individuals in large tracts, and as cultivation was not enforced, and no roads were made through these tracts, they interrupted the course of improvement. Under the old system, lands in the colony of the Cape of Good Hope, amounting to upwards of thirty-one million acres, have been disposed of for less than 46,000*l.* In Prince Edward's Island the whole of the land was granted in one day to absentee proprietors upon terms which have never been fulfilled. The influence of these proprietors with the Home Government prevented such measures being adopted as were calculated to enforce the settlement of the grants, and consequently the greater part of them remained chiefly in a wild state. ('Report of Mr. C. Buller, M.P., to the Earl of Durham, on Public Lands in British North America,' 1838.) This report contains an account of the system of granting lands in each of the provinces of British North America; and in all of them it appears to have been injurious to the public interests.

In January, 1840, commissioners were appointed under the royal sign manual to act as a Land and Emigration Board. The sale of the waste lands of the Crown throughout the British colonies was regulated by the commissioners, and they applied the proceeds of such sales towards the removal thither of emigrants from this country, when the land-fund was appropriated to this object. This board was a subordinate department of the Colonial Office. But the disposal of the waste lands is now, by various acts of the imperial and provincial parliaments, vested in the local governments. The regulations vary considerably in their details, but we give a summary of the conditions and prices of the waste lands in the North American, Australian, and Cape of Good Hope Colonies.

Colony.	Mode of Sale.	Price per Acre.
North American Colonies:		
Canada (West) . .	Fixed price . .	4*s.* to 20*s.* currency.
Canada (East) . . .	Ditto . . .	2*s.* to 4*s.* do., according to situation.
Nova Scotia . . .	Ditto . . .	1*s.* 9*d.* sterling.
New Brunswick . .	Auction and private sales . . .	2*s.* 5*d.* sterling upset price, and 2*s.* 1*d.* at private sale.
Newfoundland . . .	Ditto . .	2*s.* currency upset price.
Prince Edward Island . .	Private contract .	5*s.* and upwards, according to situation.
Australian Colonies:	By Auction. Country lands not sold at the public sales may afterwards be bought at the upset price as a fixed price.	Lowest upset price, 1*l.* sterling.
New South Wales .		
Victoria . . .		
Western Australia .		
South Australia . .		
Tasmania . .		
New Zealand [Crown lands] . . .	Auction, for town, suburban, and rural lands. Fixed price for country lands.	Highest fixed price, 10*s.* an acre.
Cape of Good Hope. .	Auction, subject to a quit-rent . .	No fixed upset price.
Natal	Ditto . .	Lowest upset price, 4*s.* sterling.

In Canada there are detached Clergy Reserves for sale in most of the townships surveyed prior to 1841. These reserves are now vested in the Colonial Government by the 16 Vict. c. 21 (1853), subject to the rights of the clergy. They are now thrown open for public sale. The lands reported by the chief agent for emigration at Quebec to be most worthy the attention of emigrants, are the townships Peel, Wellesley, Maryborough, and Mornington, covering an area of 250,000 acres, in the county of Waterloo. The prices of land in these townships (as of all clergy reserves), are regulated by the quality of soil and situation, and average from 8*s.* to 20*s.* currency per acre, one-tenth of the purchase-money being required at the time of sale, and the remainder to be paid in nine annual instalments, with interest. One million acres of land were also appropriated for school purposes by the legislature in 1849, and the school lands in the counties of Bruce, Grey, and Huron, are now open for sale to actual settlers upon the following terms:—The price to be 10*s.* per acre, payable in ten equal annual instalments, with interest. The first instalment to be paid upon receiving authority to enter upon the land. Actual occupation to be immediate and continuous. The land to be cleared at the rate of 5 acres annually for every 100 acres during the first five years. A dwelling-house at least 18 feet by 26 to be erected. The timber to be reserved until the land has been paid for in full and patented, and to be subject to any general timber duty thereafter. A licence of occupation, not assignable without permission, to be granted. The sale and the licence of occupation to become null and void in case of neglect or violation of any of the conditions. The settler to be entitled to obtain a patent upon complying with all the conditions. Not more than 200 acres to be sold to any one person on these terms.

In Canada West, the provincial government have opened three great lines of road, and laid out for settlement the lands through which they pass. They are styled—1st, The Ottawa and Opeongo Road, which runs east and west; it will eventually be 171 miles in length, and connect the Ottawa River with Lake Huron. 2nd, The Addington Road, which runs north and south, is 60 miles long, and starts from the settlements in the county of Addington until it intersects the Opeongo Road. 3rd, the Hastings Road, which runs nearly parallel to the Addington Road, is 74 miles long, and connects the county of Hastings with the Ottawa and Opeongo Road. In order to facilitate the settlement of this part of Canada, and to provide for keeping the roads in repair, the provincial government have authorised free grants of land along these three roads, not to exceed in each case 100 acres, upon the following conditions: That the settler be eighteen years of age. That he take possession of the land allotted to him within one month, and put in a state of cultivation at least twelve acres of the land in the course of four years; build a house, at least 20 by 18 feet; and reside on the lot until the conditions of settlement are duly performed. Families comprising several settlers entitled to lands, preferring to reside on a single lot, will be exempted from the obligation of building and of residence (except upon the lot on which they live), provided that the required clearing of the land be made on each lot. No title is given to the settler until after these conditions have been performed, and the non-performance of them entails the immediate loss of the assigned lot of land, which will be sold or given to another.

The road having been opened by the government, the settlers are required to keep it in repair. The log-house required by the government to be built is of such a description as can be put up in four days by five men. The neighbours generally help to build the log-cabin for newly-arrived settlers without charge, and when this is done the cost of erection is small: the roof can be covered with bark, and the spaces between the logs plastered with clay and white-washed; it then becomes a neat dwelling, and as warm as a stone house.

The lands in Canada West thus opened up for settlement are capable, both as to soil and climate, of producing abundant crops of winter wheat of excellent quality and full weight, and also of every other description of farm produce grown in the best cultivated districts of that province.

In Australia and New Zealand, licences and leases are granted for large tracts of land for pasturage purposes, at very low rents, as to which the holders have certain restricted rights of pre-emption if required for purposes of cultivation, and subject to the right of being taken by the government if wanted for public purposes.

In all the colonies the rights of the crown in regard to minerals are preserved; but in most cases leases are granted on payment of a certain rate per cent. on the produce. In Australia, licences to mine and dig for gold on crown lands are granted at the rate of 10*s.* per month for each individual licence, payable in advance; or in case of a lease being granted of a certain portion of land, at a rate of 3 per cent. on the gross value of the gold procured from crown lands, and of half that amount on gold obtained from private lands. A "miner's right" licence to search and dig for gold is obtainable on payment in advance of 1*l.* per annum. "Storekeepers' licences" at the "Diggings" are also paid for at the rate of 2*l.* 10*s.* for three months, 5*l.* for six months, and 10*l.* for twelve months.

The Land and Emigration Commissioners are required by their official instructions to prepare and issue "a distinct and compendious account of whatever relates to the agriculture, the commerce, the natural products, the physical structure, and the ecclesiastical and political institutions of each of the colonies in which they offer land for sale." The Commissioners, in pursuance of this object, issue occasionally a 'Colonisation Circular,' which contains matter calculated to be of essential use to emigrants or persons who intend at some time to settle in the colonies.

EMPANNEL, the writing and entering the names of a jury on a parchment schedule or roll of paper by the sheriff. [PANEL.]

EMPEROR, from the Latin *imperátor*. Among the early Romans the title of Imperator was bestowed by the acclamations of his soldiers in the camp, and by a vote of the Roman senate, on a commander-in-chief who had signalised himself by killing a certain number of the enemy. (Tacit. 'Annal.' iii. 74.) The term was gradually extended to signify a commander-in-chief sent on any important expedition. (Cic. 'Pro Lege Manil.,' c. 2.) But it still continued usual for the appellation to be bestowed as a special title of honour for some military service; thus we find that the small military exploits of Cicero conferred on him the title of Imperator. C. J. Cæsar assumed the name as a prænomen (Imperator C. J. Cæsar), a practice which was followed by his successors, as we may observe on their coins. (Suetonius 'Cæsar,' 76.) As examples of this title see the coins of ANTONIUS, AURELIUS, &c., in BIOG. DIV. On the reverse of the coin of Aurelius we observe Imp. VIII., that is, Imperator octavum, or imperator the eighth time, which shows, as indeed can be proved from a variety of examples, that the Roman emperors often assumed the title on special occasions when they or their generals had obtained some signal victory. This term Imperator then, it will be observed, under the early emperors, cannot be considered as denoting any sovereign power. It was indeed given to private individuals on the occasion of great military success, certainly as late as the time of Hadrian, and perhaps later. (Appian 'Civil Wars,' lib. 2.)

After the time of the Antonines the term Imperator seems to have gradually grown into common use as one of the titles which expressed the sovereign of the Roman world, though the name Princeps was also long used as indicating the same rank and power. (See the Dedication of J. Capitolinus to Constantine.) It may be difficult to state when this term Imperator became exclusively the designation of the Roman sovereign. In the introduction to the Digest (De Conceptione Digestorum), Justinian assumes the title of Imperator Cæsar Flavius Justinianus, &c., semper Augustus. [AUGUSTUS, in BIOG. DIV.] In the proëmium to the Institutes, Justinian uses the terms Imperatoria majestas to express his sovereign power, and yet in the same paragraph he calls himself by the name of Princeps, a term which dates from the time of the so-called Republic, and expressed the precedence given to one particular member of the senate. The term Princeps was adopted by Augustus as the least invidious title of dignity, and was applied to his successors.

From the emperors of the West this title, in the year 800, devolved to Charlemagne, the founder of the second or German empire of the West. Upon the expiration of the German branch of the Carlovingian family, the imperial crown became elective, and continued so until the last century. The title of emperor of Germany now no longer exists, Francis II. having laid it aside, and assumed the title of emperor of Austria. [AUSTRIA, in GEOG. DIV.] The only other European potentates who use the style of emperor are the autocrat of Russia, the monarchs of which country, about the year 1520, exchanged their former title of duke or great duke of Russia for that of Czar or Tzar; and the emperor of the French. In early times it was asserted by the civilians that the possession of the imperial crown gave to the emperors of Germany, as titular sovereigns of the world, a supremacy over all the kings of Europe, though such was never attempted to be exercised; and they denied the existence of any other empire: but in spite of this denial it is certain that several of the kings of France of the second race, after they had lost the empire of Germany, styled themselves Basileus and Imperator. Our own king Edgar, in a charter to Oswald, bishop of Winchester, styled himself "Anglorum Basileus omnium que regum insularum oceani que Britanniam circumjacentis cunctarum que nationum quæ infra eam includuntur *Imperator et Dominus*." Alfonso VII. also, in the 12th century, styled himself emperor of Spain. It might be easily shown how the title and rank of king and emperor have been feudalised, as it were, in passing through the ordeal of the middle ages.

EMPHASIS, in articulation, is the mode of drawing attention to one or more words in a sentence by pronouncing them with a greater volume and duration of sound, and in a higher or lower note, than the adjoining words. In written language there are several symbols by which emphasis is denoted. In manuscript the emphatic word is commonly underlined; in printing it is common to employ a different character, particularly the inclined character called the italic. The German printers have introduced the mode of placing the letters of the emphatic word farther apart from one another. In modern languages the employment of some symbol for emphasis is more requisite than in the ancient languages. In the latter, where the arrangement of words was less fixed, it was generally practicable by the very position of a word in a sentence to denote its emphatic power. Thus, in the Latin language, the first word of a sentence, or even of a clause, is generally emphatic; so also is the last word; and even in the middle of a sentence the verb is often so placed as to give emphasis to the preceding word.

EMPHYTEUSIS (*ἐμφύτευσις*). The term expresses in the Roman law a perpetual right to the enjoyment of land, on condition of paying annually a fixed sum (canon vectigal, pensio) to another person who was considered the owner of the land, and of keeping the land itself in good cultivation. Some writers, indeed, have explained the term to be property in *waste* lands, given on the condition of cultivating them and paying a certain rent. Savigny, whose deep researches into the Roman law, have thrown light upon many obscure and imperfectly understood passages, by contrasting the right of emphyteusis with the tenants of the Ager Vectigalis, has shown the important bearing of each of these kinds of possession the one upon the other, maintaining that both of them are to be considered not as a species of property (like land in the provinces), but as rights *jura in re*; for the Roman jurists, he says, expressly ascribe to the hereditary tenant a *jus in fundo* or *jus prædii*; who in the imperial constitution is always distinguished from the dominus (the landlord). The occupier was called emphyteuta, and the owner of the land dominus emphyteuseos.

The title of the emphyteuta depended on his paying what he had contracted to pay, and also all the taxes to which the property was liable. If he neglected to pay these dues for three years he might be ejected out of the land by the owner, without having any compensation for his improvements. He could alienate the land after giving notice to the owner, who might, however, if he pleased, take the land at the price of the emphyteuta. If he did not, then the emphyteuta could sell it to any person who was able to answer all the demands to which the land was subject by virtue of the contract. In each case the owner was bound to receive the purchaser as his emphyteuta, and confirm his title in due form, for which he could claim a payment not exceeding a fiftieth part of the price at which the land was sold.

The relation between the emphyteuta and the owner originated either in a direct grant from the dominus to the emphyteuta, made either in the form of an agreement or by way of actual conveyance and delivery (*traditio*), or else by the emphyteuta acquiring a prescriptive right by a tenancy of 10 or 20 years' duration, in which case a grant made by one who was not the dominus became valid and effectual at the end of the above period. The owner could also make an emphyteusis by his will.

The emphyteutic contract does not appear in its special form till the reign of Zeno, for though it had an earlier existence as a contract, yet its nature had been much discussed, and whether it was like *locatio conductio*, or like *venditio*, could not be settled till Zeno first, and after him Justinian, gave it a special name and a peculiar action. The Digest is the oldest extant authority in which the term emphyteusis occurs, s. 27, 9, 3, 4. The use and enjoyment expressed by the word emphyteusis were always carefully distinguished from ownership; the emphyteuta was a perpetual lessee who paid a perpetual rent to the owner.

(The subject of the emphyteusis is discussed in the *Inst.*, 3, 24, 3; *D.* 6, 3; *D.* 39, 4; *Cod. Theod.*, 10, 3; *Cod. Justin.*, 4, 66; Mühlenbruch, *Doctrina Pandectarum*; Savigny, *Das Recht des Besitzes*, p. 99, &c., 5th ed.; and Mackeldey, *Systema Juris Romani*. The reader is also referred to a learned note in Hargrave and Butler's edition of *Coke upon Littleton*, 64 a (n. 1), and 191 a (n. 1); to Sir F. Palgrave's *English Commonwealth*, ii., 208; and to Mr. Hallam's *History of Europe during the Middle Ages*, 10th edition, vol. i., p. 314, et seq.)

EMPIRIC. This word is derived from the Greek (*ἐμπειρικὸς* empeirikos), and means a man who derives his knowledge from experience. A medical sect which arose in opposition to that of the dogmatics assumed the name of empirics. Serapion of Alexandria and Philinus of Cos are regarded as the founders of this school. Ever since the world has existed, the human mind, in striving to find out the principles of truth, has considered the matter in two opposite ways. According to one system, the human mind contains the seeds of knowledge; according to the other, the mind is nothing but a blank sheet of paper, on which experience writes that which man perceives through the senses. Aristotle and Plato are still the representatives of the two opposite systems.

The science of medicine has been of necessity under the influence of one of the two opposite opinions, and the doctrine of Serapion or Philinus is nothing but the application of the Aristotelian theory, that nothing can be known by the understanding which has not been previously known by the senses.

Accordingly they maintained that experience was the only true knowledge which was derived from the unerring testimony of the senses; that dogmatism was erroneous, because it derived its principles from mere imagination. They opposed to the theorists their contradictions, and sneered at their learning and acuteness of reasoning as inadequate means of curing diseases.

The empirics admitted three kinds of experience, the one acquired by chance, the second by experiments, the third by imitation; and these three they called the tripod of medical science. However, it is evident that their mode of experience is nothing but a disguised mode of reasoning by analogy. Epilogism, as they called it, is as theoretical as pure dogmatism; for, how can we judge by analogy, if we do not assume some general laws to which the particulars are subjected?

If the empirics had remained true to their principles their name would stand high among the medical profession. But having abandoned the study of nature, and with it all scientific pursuits, they sank into such disrepute, that their name became a stigma. And even in our days when the natural sciences have, by the impulse given by Lord Bacon to genuine experiment, risen to a high degree of perfection, and empiricism is the character of modern science and philosophy, the name of empiric is still bestowed as an opprobrious term upon all ignorant pretenders in the medical art.

(Curt Sprengel, *Geschichte der Medizin.*)

EMPYE'MA (*ἐμπύημα*, from *ἐν*, 'in,' and *πῦον*, 'pus,' a word which signifies an internal collection of pus). Although this term was restricted by the ancients to purulent collections in the thorax, it is now employed to signify all collections in the pleura which do not arise from an obstruction to the circulating system, and are not of a gaseous nature. In a natural state the pleura, like other serous membranes, secretes a clear fluid, which is removed by absorption as quickly as it is formed. But from the existence of inflammation or the presence of foreign bodies, other fluids often accumulate. The most common of these are serum, blood, pus, and fibrinous matter. Any of them may be present alone, or may be mixed in varying proportions. It is, however, almost impossible to ascertain by any external means the nature of the fluid which has accumulated. Dr. Townsend relates two cases of empyema: in the one, a case of two months' standing, produced by the bursting of a tubercular abscess in the lungs; on the fluid being removed, it presented all the characters of pus; in another case, arising from the same cause, a perfectly transparent and colourless fluid was found. It is therefore not only difficult to discover the nature of the fluid, but the same exciting cause may give rise to the presence of different kinds of fluid.

Whatever may be the nature of the fluid in the lungs, it always exists in conjunction with a peculiar state of the pleura. This membrane is covered over to a greater or less extent with a fibrinous secretion, which, in this and other cases becoming organised, constitutes what are known by the name of false membranes. This fibrinous matter is sometimes deposited in so large quantities on the pleura, which covers the lungs, that even after the fluid is removed, the lungs, which have been compressed, cannot expand, and consequently the parietes of the chest fall in and occupy the vacant space, and contraction of the chest is produced. The false membranes thus produced are liable to various diseases, and they may inflame, ulcerate, or become ossified, and thus produce various secondary diseases. Sometimes the false membranes extend from one side of the cavity of the pleura to the other, and a case is related by Dr. Townsend of a person "in whom the effusion was divided by these partitions into three compartments, so perfectly distinct from each other, that had the operation of paracentesis been performed during life, that compartment only could have been evacuated into which the incision had been made; so that in order to draw off the entire effusion it would have been necessary to perform three several operations."

The worst effect of the presence of fluid in the pleura is exerted on the lung. By its pressure the lung becomes incapable of expanding for the admission of air. Its position is generally by the side of the spinal column, but through the deposition of the fibrinous matter the pleura of the lungs and of the ribs often contract adhesions, and in this manner the lungs may be forced to occupy very varied positions in the cavity of the thorax. When the effusion is extensive the lung becomes flattened and flaccid, its surface is corrugated, and its tissue becomes soft, pliant, and dense, exhibits no crepitation, and is almost entirely deprived of blood. It does not often inflame in this state, but frequently becomes the seat of the deposition of tuberculous matter.

Empyema is always attended with inflammation acute or chronic of the pleura [PLEURITIS], although the bursting of an abscess or the wounding of a blood-vessel may assist in producing the accumulated fluid contents of the pleura; at the same time it frequently happens that the inflammatory symptoms are of so mild and insidious a nature that they are entirely overlooked. This was more frequently the case previous to the use of percussion and auscultation than at the present day. It is in fact impossible by general symptoms alone to infer the presence of empyema. The following symptoms however, taken with the physical signs, may be regarded as characteristic:—Difficult respiration, increased by motion, exertion and lying on the sound side; fulness and oppression at the chest; enlargement of the diseased side; protrusion of the intercostal spaces, with an obscure sense of fluctuation and œdema of the integuments; dulness of sound on percussion, and absence of the respiratory murmur on the diseased side, which remains perfectly motionless; noisy respiration in the opposite lung with violent action of the respiratory muscles; displacement of the heart; protrusion of the abdomen; a harassing short cough, small rapid pulse, and the other symptoms of hectic fever. To these symptoms some would add ægophony, a sound on speaking like the bleating of a goat, but this only occurs when there is a thin stratum of fluid in the pleura, and it is absent when the empyema is extensive. The intensity of all these symptoms is proportionate to the quantity of fluid effused, the duration of the disease, and the constitutional strength of the patient. The difficulty of breathing is in proportion to the quantity of the fluid which presses on the lungs. The inability to lie on the sound side arises from the pressure of the fluid upon the sound lung when a person lies so that its weight comes directly upon it. The cough is not a constant symptom, and may be entirely absent where there is no inflammation of the lungs or bronchiæ. The hectic symptoms will vary according to the strength of the individual and the duration of the disease. Night-sweats do not occur in conjunction with the other hectic symptoms in empyema, unless the lung is in a state of tuberculous ulceration.

There are few diseases with which empyema is likely to be confounded. Its general symptoms resemble those of tubercular phthisis, but the history of the disease, and more particularly the stethoscopic signs will point out the distinction. In phthisis there is no displacement of the heart; absence of the respiratory murmur is usually found at the upper part of the lung, and is followed by mucous râle, pectoriloquy, &c. Hepatisation of the lungs has been referred to as likely to be confounded with empyema, but this is so rare a disease in a chronic form, as to render it unnecessary to point out the distinction between the two diseases here. The same remark applies also to tumours in the sac of the pleura, which, although they have been recorded, are too rare to need a description. Enlargement of the liver, with that organ pressing upon the diaphragm and lungs, might produce the same symptoms as in empyema, but a careful examination in connection with hepatic symptoms would soon indicate the diagnosis.

The treatment of empyema may be of two kinds, medical and surgical. The general principles on which the first should be conducted are those which would be applied in pleuritis. [PLEURITIS.] It, however, often happens that the resources of medicine fail, and that no other chance of relief can be offered the patient than that of drawing off the effused fluid by means of an operation. This is called the operation of empyema, or paracentesis thoracis. This operation, although in modern times it has got much into disrepute, was performed by Hippocrates (Hipp., 'De Morbis,' lib. ii. 576; Galen, 'Comment.,' Aph. 27) and the older practioners of surgery with apparently much success. It has recently been recommended, especially by Laennec, in cases of empyema which do not offer a chance of being cured by medical treatment. In such cases, where all other remedial means have been tried, there seems an increasing conviction that this operation may be had recourse to with every chance of benefit: and cases have now been recorded, both in the practice of the French and English hospitals, in which a large proportion of those operated on have recovered. Another class of cases in which paracentesis has been recommended, are those in which the empyema is dependent on acute inflammation of the pleura, and in which the fluid accumulates so rapidly as to threaten suffocation unless removed.

In the performance of paracentesis, the most eligible spot for the operation is between "the fifth and sixth, or the sixth and seventh true ribs, at the point just in front of the indigitations of the serratus magnus, or midway the anterior and lateral parts of the chest." Some surgeons however recommend that it should be done between the third and fourth ribs on the left side, and the fourth and fifth on the right, as they suppose there is danger of wounding the liver or diaphragm by operating lower down. The integuments should be drawn on one side, if it be intended that the wound should close after the operation, and the incision through them should be about two and a half inches long. The intercostal muscles will thus be exposed, and should then be cautiously divided; and when the pleura which lines the ribs is exposed, a small puncture should be carefully made in it. In dividing the intercostal muscles, the knife should be kept close to the upper edge of the lower rib, in order to avoid the risk of wounding the intercostal artery, which runs in a groove upon the lower edge of the upper rib. The size of the opening into the pleura must be regulated by the nature of the effused matter. A canula, supplied with a stopper, should then be introduced and kept in the wound, so that the whole or a part of the fluid may be drawn off.

(*Cyclopædia of Practical Medicine*, article 'Empyema;' Cooper, *Dictionary of Surgery; First Lines of Surgery.*)

EMPYREUMA denotes the peculiar and disagreeable smell and taste resulting from the action of a considerable degree of heat upon vegetable or animal substances in close vessels, which prevent such an access of air as is required for perfect combustion: in this way destructive distillation goes on so as frequently to produce an oil which has a strong, burnt, or, as it is termed, empyreumatic smell and taste.

EMULSIC ACID. [FERMENT, *Emulsin.*]

EMULSIN. [FERMENT.]

EMULSION, a term applied to mixtures which generally have a milky appearance, and which in some cases, are partial solutions, in others merely mechanical suspensions of oily or resinous substances: thus, the oil of the almond seed may be for a time diffused through water by trituration, but will ultimately separate and float on the surface. Many resins are formed into emulsions by means of the yolk of an egg, or of gum-arabic; while gum resins contain in themselves the means of forming emulsions with water. Frequently syrups and distilled waters are added to render the compound more palatable; but alcohol and acids should never be used. Emulsions should be used soon after being formed, as in a few hours the constituent parts separate or become acid. Almonds and some other substances are directed to be kept in the state of dry confections [CONFECTIONS], and these can immediately be formed into emulsions by trituration with either pure or distilled aromatic waters. Castor oil may readily be made into an emulsion by merely mixing it, and stirring it well, in warm milk or coffee. By this means it not only acts more rapidly, but a much smaller dose is required. It can also be formed into a real emulsion by mixing it in any aromatic water, such as dill or cinnamon, to which a few drops of caustic potass (liquor potassæ), have been added. But in this latter case, the large ordinary dose is needful.

EMYDIN. A neutral azotised substance contained in the yolk of tortoises' eggs, and bearing a considerable resemblance to ICHTHIN. According to the analysis of Fremy, it consists of

Carbon	49·4
Hydrogen	7·4
Nitrogen	14·6
Oxygen Phosphorus	

Emydin presents the appearance of white, hard, and transparent grains, very soluble in dilute solution of potash. It dissolves in boiling hydrochloric acid, without producing a violet colour; in acetic acid it swells up, but does not dissolve. On incineration it leaves about one per cent. of a calcareous ash.

ENAMELS AND ENAMEL-WORK. The subject of this article will best be treated under three sections—Enamels, in their character and mode of employment; enamel-painting, as a branch of the fine-arts; and enamelled-ware, as a manufactured product.

1. *Enamels.*—These are vitrifiable substances, or a peculiar preparation of glass, to which different colours are given, sometimes preserving, sometimes depriving it of its transparency. Artists and jewellers distinguish three kinds of enamels; those which are used to imitate precious stones, those employed in enamel painting (painting on enamel), and those with which an infinite variety of small works are made. The preparation of enamels is very various. In general, ten parts of lead and three parts of tin are oxidised by continued heat and exposure to air. To the mixed oxides thus obtained must be added ten parts of powdered quartz or flint and two parts of common salt, and the whole must be properly melted in a crucible; thus we obtain a white enamel and the basis of coloured enamel, metallic oxides being added in the preparation at the very beginning to give the required colour. The addition of oxide of lead or antimony produces a yellow enamel; reds are obtained by a mixture of the oxides of gold and iron, that composed of gold being the most beautiful and durable. The oxides of copper, cobalt, and iron, give greens, violets, and blues; and a great variety of intermediate colours is produced by mixing them in different proportions. The oxides are sometimes mixed before they are united to the vitreous basis. These are the principal ingredients in the composition of enamels; but the proportions in which they are used, the degree and continuance of the heat required for their perfection, are secrets which the manufacturers carefully keep to themselves as far as they are able.

The art of practically applying these enamels is of great antiquity. It was practised by the Egyptians, from whom it probably passed to the Greeks, and subsequently to the Romans, who are supposed to have introduced the art into Britain. The art continued to be practised by the Byzantines and by the ecclesiastical artists of the middle ages. In this country it was in use among the Britons, the Saxons, and the Normans successively, as is proved by various specimens still existing; and thence down to our own times. Anciently enamels were principally applied to ornamental purposes; but since the invention of clocks and watches their usefulness has increased in an extraordinary degree, there being probably no substance for dial-plates equal to enamel in durability and beauty. The various processes in the practice of enamelling, like the composition of enamels noticed in the last paragraph, have probably never been completely made known to the public; they require extraordinary care and attention, and artists who may have been so fortunate as to discover any improved mode of operating are commonly too jealous to make it known.

Enamels being commonly laid on a metal ground, the first business is to prepare the plates, technically called *coppers*, to receive the enamel. This preparation requires much care and nicety, and the process is extremely curious. The metals used to enamel upon are gold, silver, and copper. Of the other metals some are too fusible to bear the fire, and the others, as platinum, &c., are too *strong*, as it is termed, for the enamel. The best substance to enamel upon is gold, the richness of the colour giving a beautiful tinge through the enamel; but, except for watch-cases and valuable articles of jewellery, copper is generally used on account of its cheapness. Both the gold and the copper should be of the finest kinds.

Enamelling is divided chiefly into two branches, dial-plate enamelling and transparent enamelling; the former including the manufacture of clock and watch plates, with fluxed plates for enamel painting; the other the enamelling of watch-cases, brooches, and other trinkets. The artistic branch is noticed here; various applications to the useful arts will be treated in the latter part of this article. The enamel as it comes from the maker is commonly in small cakes four, five, or six inches in diameter. In preparing it for use it is split, by means of a small hammer applied to the edge of the cakes, into thin flakes, which are put into an agate mortar and finely pulverised; the powder is then washed with water. The moistened mass is laid very smooth on the metal ground with a spatula, and when dried is melted, or, as it is called, *fired*, under a muffle, in a small furnace heated with coke and coal. The back of the coppers is first covered with enamel, and then the face, to which two coats are given, the operation of firing being applied to each. The plates are then carefully polished, for which various substances are used; and when this is complete, they are put for the third and last time into the fire before painting.

2. *Enamel Painting.*—Supposing an enamelled gold or copper plate to have been prepared, we have next to notice the difficult and delicate process of enamel painting. This art, which should be called painting on enamel, is of modern date. It has indeed been supposed that the encaustic painting of the ancients was the same thing as our enamel painting. But though the ancients possessed the art of colouring glass, which might have led to enamel painting, they do not seem to have acquired this latter art, the invention of which, as it is practised in our days, is ascribed to the French. In 1632, Jean Toutin, a goldsmith at Châteaudun, painted on enamel; and he and his disciple, Gulden, taught others. Jean Petitot, born at Geneva in 1607, an admirable painter in miniature, carried the art of painting on enamel to a degree of perfection never before attained. He resided long in England; and French writers affirm that he obtained the knowledge of the most beautiful and durable colours for enamel painting from Sir Theodore Mayence, at London, an eminent physician and chemist, who generously communicated his secrets to him, and recommended him to Charles I. After the king's death Petitot went to Paris, where he was highly favoured by Louis XIV., and gained a large fortune. Consequent on the revocation of the edict of Nantes he withdrew to Geneva.

Mr. Digby Wyatt, in a paper read before the Society of Arts, has traced the progress of artistic enamelling, from the time when it was merely a kind of mosaic work, down to recent days, when the resources of the painter are brought to bear upon it. He traces six stages or leading varieties, succeeding each other in a definite order; they were marked by attempts either to improve the fixature of the vitreous paste on its metallic base, or to increase the external adornment. The first, or *Byzantine* style, was practised throughout the Eastern empire from the time of Justinian down to about the year 1300. The best known works of this kind were executed by Theophilus, the celebrated artist-monk of the 11th or 12th century. The chief peculiarity of the process was in the formation of cavities or cells of gold filagree, for the reception of the enamel. The second, or *Early Limoges* style, was much practised in that city from the 11th to the 14th centuries; it consisted in forming incisions in a thick copper plate by the graver, for the reception of the enamel, in substitution of the Byzantine or filagree method. The third, or *Early Italian* style, was practised from about the close of the 13th century to that of the 16th. The most celebrated artist in this method was Ugolino Veri, who executed the shrine in the Orvieto Cathedral in 1338; but it was afterwards much practised by goldsmiths and enamellers. It appears to have occupied a midway position between the ancient *champ levé*, or incised enamel, and the painted enamels afterwards produced; it consisted in engraving on silver after the manner of medallic relief, and then floating it over with variously coloured transparent pastes. The fourth, or *Jeweller's* style, was either actually invented by Benvenuto Cellini, or he at least was the first to describe the improvement that took place in the enamelling art about the beginning of the 16th century. This method consisted in the use of a particular vehicle or liquid with the glass powder employed to cover small gold or silver objects in the round or in very high relief; the vehicle consisted of water in which the pips of pears had been steeped; the paste was held in its place until vitrification took place, and was yet so delicate a cement as in no degree to interfere with the perfect purity of the enamel. The fifth, or *Late Limoges* style, sprang at once from the inventive genius of Leonard Limousin, under the auspices of Francis I. It differed from the preceding styles chiefly in this: that the surface of the metal was entirely covered with an opaque paste, on which paintings were executed in transparent colours; the effect of a translucent ground was then obtained by applying silver leaf in particular situations, fixing it with a glaze of coloured enamel, and finally tinting over it. In the hands of a true artist, this method was susceptible of beautiful results; but it degenerated into tawdriness under the Nouailhers, a family of enamellers who lived during the latter part of the 17th century. The sixth, or *Miniature* style, was that which Petitot, the enameller mentioned in the last paragraph, was the first to bring to a high state of excellence. The chief characteristics of this style were, a great enrichment by the addition of new pigments, a power of multiplying the number of firings, a more minute graduation of tints, and an increasing modification in hardness and fusibility by means of fluxes. This, in the present day, is the chief kind of enamel-work, considered as a branch of the fine arts.

The painting on enamel is in itself virtually enamelling; for the pigment employed is an enamel, or glass, or vitrifiable substance, coloured with various metallic oxides, chlorides, and salts (no vegetable or animal colours being employed). The coloured pieces of enamel are ground up very finely in an agate mortar with oil of lavender, or some other liquid; and the paint thus prepared is laid on with a fine camel-hair pencil. The heat of an oven is finally employed to fuse it, and the enamel-paint becomes firmly incorporated with the enamel-ground.

The difficulty of preparing the plates for enamel painting, and more especially the care and caution required in burning in the colours, with the very great risk attending the operation, had, till recent times, restricted the ordinary size of fluxed plates, and consequently of enamel paintings, to five or six inches; and French writers think it would be little short of madness to attempt such works on a larger scale. But English artists have of late years so far exceeded these limits, that it would be absurd to hazard any dogmatic opinion respecting the possible extent to which they may go. The late Mr. Horace Hone was, we believe, the first who ventured much to exceed the usual size; he produced a beautiful whole length portrait of a lady, which was about twelve inches high, and broad in proportion. But this was far exceeded by the late Mr. H. P. Bone, whose copy from the famous picture of Bacchus and Ariadne by Titian, in the National Gallery, measures 18 inches by 16½. Mr. Bowles became the purchaser of this enamel for the enormous sum of 2200 guineas. The same artist had also in the exhibition of the Royal Academy, in 1837, a copy of the Virgin and Child, by Vandyke, of still larger dimensions. Mr. Charles Nurse produced a copy in enamel of a Holy Family after Parmigiano, measuring 20½ inches by 15¼; George IV. purchased this for 1500 guineas.

When we contemplate such works finished in the most exquisite manner, we cannot but admire the courage of the artist in undertaking them. The brilliancy and permanency of the colours are indeed a great temptation and an ample reward for success. But chances of failure are great, and increase with the size of the work, which is not safe till it has undergone the operation of being exposed to the fire for the last time. Indeed the whole process from the very outset requires in every stage the utmost care and attention, and a degree of skill in the management which only long practice can give. No fault in the design can be corrected; the artist's conception must be traced in the first instance with perfect accuracy; the fire may destroy the work, but what it fixes, whether good or bad, is unalterable.

3. *Enamelled Ware.*—A process is now extensively practised of enammelling the interior of cast-iron and other hollow articles, such as saucepans and other culinary and domestic utensils. The superior cleanliness of such articles, and the security which they afford against any metallic taint, render them peculiarly valuable for some delicate operations in cookery and confectionary, and for the preparing of pharmaceutical decoctions, extracts, &c. A patent was obtained in 1799 for two modes of performing this process, by Dr. Hickling; but though the manufacture of enamelled wares was carried on for some time under this patent, it was at length given up, for want of due encouragement. A second process was patented by Messrs. Thomas and Charles Clarke, in 1839, for applying an enamel lining less liable to crack or split off with the action of fire than that commonly used. According to their specification the vessels are to be first thoroughly cleansed by exposing them for three or four hours to the action of dilute sulphuric acid, and then boiling them for a short time in pure water. The first enamel composition is then applied. It consists of 100 lbs. of calcined ground flints, and 50 lbs. of borax, also calcined, and finely ground with the flint; this mixture is fused and gradually cooled, after which it is ground in water with the addition of one-eighth of its weight of potter's clay, until the mixture forms a mass of a pasty consistence. This coat is set by placing the vessel in a warm room, after which, while it is yet moist, the second or glazing composition is sifted finely and evenly over it in the form of a dry powder. This glazing composition consists of 125 lbs. of white glass (without lead), 25 lbs. of borax, and 20 lbs. of soda (crystals), all pulverised together, vitrified by fusion, ground, cooled in water, and dried. To 45 lbs. of this mixture 1 lb. of soda is added; the whole being then mixed together in hot water, and when dry, pounded to prepare it for sifting on the vessel as above stated. The vessel is then dried in a stove at a temperature of 212° Fahr., and subsequently heated gradually in a kiln or muffle resembling that used for glazing china, until the glaze is fused or fluxed. Sometimes the glaze-powder is again dusted over the fused glaze, and fluxed a second time in the kiln. Some other manufacturers, having produced enamelled ware of excellent quality, were sued by the Messrs. Clarke for an invasion of their patent rights; but the patentees were non-suited in the Court of Exchequer. Indeed, the formulæ by which a good enamel may be compounded are almost innumerable, so that a patent for such a purpose seems to be untenable, or at least easily evaded. Many enamels used for this purpose possess deleterious properties, owing to the presence of lead, which was found in some of the earlier wares made under Clarke's patent, before the use of glass containing lead was avoided; but the best manufacturers now limit themselves to the employment of harmless ingredients.

However the process may be varied in detail, the general principle is always the same,—namely, that of applying a vitreous glaze, either transparent like glass or opaque like enamel, and either white or coloured, to the surface of a piece of metal very carefully cleansed and prepared, and afterwards uniting the two firmly by fusing the glaze in a kiln. The culinary and other vessels of enamelled ware are now becoming an important branch of manufacture at Birmingham and Wolverhampton. In the Official Report prepared by direction of the Board of Trade concerning manufactures in metal sent to the Paris Exhibition in 1855, the following observations occur: "In the more useful cast-iron articles, such as kitchen utensils, especially enamelled hollow ware, the exhibits of Austria and Prussia presented features which evidenced a great improvement during the last three or four years; but it is quite clear that exhibitors of these useful articles have been fully alive to the importance of improvement; and two leading representatives of this branch of industry, Messrs. Clarke of Wolverhampton and Messrs. Kenrick of West Bromwich, certainly more than sustained their position, not only by the character of the work, but also by the variety of the utensils to which they had succeeded in applying the process. The Birmingham productions of the Patent Enamel Company under Paris's patent were not represented in the Exposition. These consist of a great variety of utensils stamped in sheet iron for culinary and other purposes, the surfaces of which are covered both inside and outside with a glass enamel. Though originally a French invention, it is now likely to form an important feature in British manufactures, since it can be applied to many articles made in wrought iron which require to be protected from the atmosphere or the action of water. Plates, dishes, &c., produced by this process for table use are susceptible of any amount of decoration, in the manner and by the methods applicable to ordinary earthenware or porcelain, and are peculiarly suitable for ship purposes from their lightness and non-liability to fracture. In many decorative purposes this method of enamelling on sheet iron is likely, under proper direction, to become of great value and importance."

Enamelling hollow iron ware is the principal but not the only application of the art to useful purposes. The enamel for watch-dial faces, adverted to in an earlier paragraph, is often distinguished as *glass* enamel. It derives its whiteness, not from tin and antimony, like artists' enamel, but from arsenic; the substance thus produced is very glassy, brittle, easily scratched, readily fusible, and very white. It is not at all suited for coating culinary vessels, but renders excellent service for watch- and clock-dials, and ornaments for the mantel-piece or the toilet-table. In the enamelling of dials, the enamel is first broken into small pieces with a hammer, and then pounded with an agate pestle and mortar. A plate of copper is prepared of the proper size and shape; the enamel-powder is spread evenly upon it; the plate is exposed to heat, and the enamel adheres firmly to the metal. For the best kinds of dial-faces a second coating of enamel is laid over the first. The figures or numerals which belong to a watch or dial are painted with a vitrifiable colour, somewhat in the same way as artistic enamel-painting, after which the heat of a kiln, melting the colour and softening the enamel, incorporate the two into one body.

We may advert in this place, as belonging quite as much to the enamelling art as to that of earthenware or porcelain, to the Baron du Tremblay's *émail ombrant*, or *shaded enamel*, a production remarkable alike for the ingenious way in which it is wrought and for the pleasing appearance which it is said to present. It consists in flooding coloured but transparent glazes over designs stamped in the body of earthenware. A plain surface is thus produced, in which the cavities of the stamped design appear as shadows of various depths, the parts in highest relief coming nearest the surface of the glaze, and thus leaving the effect of the lights of the picture. If taste be exercised in the selection of the design, this art appears to be susceptible of many beautiful modifications.

ENCAMPMENT is the lodgment or station of an army, with its artillery, baggage, and stores, when it has taken the field for the purpose of a review, or of acting against an enemy.

Under the word CAMP (ROMAN) there has been given an account of the ancient castrametation; and, till the employment of fire-arms in war, it is probable that the manner of occupying ground for military purposes which had been adopted by the Romans continued to be used by the nations formed on the ruins of their empire, such alterations only being made in the internal arrangements of the camp as were rendered necessary by differences in the numerical strength of the principal divisions of the troops.

The camps of the Britons, and those of the Anglo-Saxons and Danes in this country, seem to have been intrenched by breast-works made of felled trees, or of earth and stones rudely heaped together. Concerning the disposition of the troops within the inclosure, we only know that the Saxons drew up their cavalry in one dense body surrounding the standard, and that they placed the foot soldiers with their heavy battle-axes in front. In a description of the camp formed by Edward II. during his expedition to Scotland in 1301, is contained the first hint we have of any regularity in the distribution of an English army while in the field; this amounts however to little more than that the ground was marked out, and that to every one his proportion of the space was assigned. Within the spaces tents of white or coloured linen were set up, and huts were constructed, the latter probably for the private soldiers. (Grose, 'Mil. Antiq.,' vol. ii., p. 205.)

In former times both the English and French commanders of armies appear to have fortified their encampments when they undertook the siege of any place, particularly if it appeared likely to be of long duration; and P. Daniel states, that when cannon were used, it was placed for the protection of the army in large redoubts of wood or earth, called *Bastilles*, constructed at intervals along the circumvallation. The same author relates that the English, while they made war in France, went by parties into the country, carrying with them strong pallisades to form an intrenchment, behind which they were protected while using their cross-bows. ('Hist. de la Milice Françoise,' liv. vii., ch. 2.)

In the modern system of war, from the necessity of avoiding as much as possible the destructive effects of the enemy's artillery, and the desire of affording all possible development to the fire of their own infantry, commanders of armies have been compelled to abandon the square form of the ancient encampments, and to adopt that of long and narrow lines. But with this arrangement it seldom happens that the ground will permit a perfect regularity in the dispositions of the several battalions and squadrons; and the occurrence of streams or other accidents of the country may break the continuity of the line, or may render it necessary to give it a bent or waving direction. When, however, an army is encamped under tents, it may be regarded as a general rule that the line should correspond to that in which the troops are to be drawn up to engage the enemy; also that the tents of each battalion should not occupy a greater space in front than the battalion itself would cover when in order of battle,—a practice which is said to have originated with Gustavus Adolphus.

The length of the front of a battalion of 750 men, two deep, allowing 21 inches to each file, will be 219 yards; and this would be the extent of the line of tents, were it not that the line is regulated by the probable number of effectives, instead of the numerical strength of the establishment. The depth of the encampment for a battalion is of less importance; but, when the ground will permit, it may be regulated by the following disposition, which is considered to afford sufficient convenience.

The tents of the privates may be ranged in two lines parallel to the front, with an interval of about 12 feet as a street between every two companies in each line, and those of the captains and subalterns may be in one line in the rear of these; the field-officers and the commanding officer may occupy a fourth line; the staff a fifth; and the line of kitchens may be in the rear of all. By this arrangement the depth, including a space for the sutler's tent, the bâtmen and horses, will be about 90 yards; but an interval of 16 yards should separate the front of the men's tents from the line of parade, which is parallel to that front. Opposite the centre of the battalion, and about 60 yards in front of the line of parade, are the tents of the party which forms what is called the quarter-guard; and at about 15 yards in rear of the kitchens the party forming the rear-guard is situated. Including all these intervals, the depth of the encampment for infantry will be 183 yards.

The length of front for a complete regiment of cavalry, consisting of eight troops, when formed two deep, is about 320 yards; and this may be considered as the extent occupied by the regiment in the line of the encampment. The seven tents of each troop are ranged in a line perpendicular to the front, and the horses are attached to pickets in lines parallel to those of the tents; the remainder of the space, reckoned parallel to the front, being occupied by the breadths of the streets. In rear of the men's tents, and parallel to the front, are arranged the subalterns' horses in one line; the tents of the captains and subalterns in another; those of the field-officers and commanding officer in a third, and the kitchens in the rear of all. The standards are placed parallel to the front at 10 yards before the tents of the privates; and the distance from thence to the line of parade is 30 yards: with these dispositions the whole depth of a regiment of cavalry will be 216 yards.

A large army is encamped in two lines which, if the ground will permit it, are parallel to, and at the distance of about 300 yards from each other; and a reserve, generally consisting of the best troops, is formed in rear of the second. The stations of the cavalry are on the flanks of each line. The artillery attached to an army is formed into brigades, and is posted either on the flanks of the camp or with the reserve in the rear; the extent of front, for a heavy brigade, is 69 yards, and the depth, including the line of guns, of limbers, and three lines of waggons, is 82 yards.

The circular tents at present in use are 13 feet 3 inches diameter within the walls (the canvas which hangs vertically between the conical part of the tent and the ground). Of the cavalry 12 men, and of the infantry 15 men, are appointed to each tent.

From a document which is supposed to be of the time of Elizabeth, it appears that then an English camp was divided into six portions, of which three were assigned to the cavalry and three to the foot soldiers; and that between every division was a street 80 feet wide. There was also a space allotted for the market, and within this was the park of artillery, surrounded by carriages. It was regulated that no man should pitch his tent within 140 feet of the ring, or periphery of the camp.

The soldiers' huts or tents were placed 25 deep; each was eight feet square, and contained two men; the depth of the encampment, including the depôts, the officers' tents, and the cross streets, was 300 feet; and, including the streets, the whole extent in front of a regiment consisting of 13 companies, each of 150 men, was 712 feet. Originally, it seems, the officers' tents were placed in front of those occupied by the men; but Sir James Turner states that Henry of Nassau changed that custom, and caused them to be placed in the rear, as they are at present, in order that the soldiers might be enabled to have more easy access to the parade in front of the line. (Grose, ii. pp. 213, 214.)

The great extent of the space which, for the reasons before mentioned, is unavoidably occupied by an army in the field, renders it, in most cases, impossible to fortify the site of the encampment by a continuous line of parapet like that with which the Roman armies surrounded themselves on taking up a defensive position; and the security of a modern army against surprises is now obtained principally by the situation being difficult of access, from streams, marshes, or inequalities of the ground, and by keeping numerous advanced posts to watch all the approaches by which an enemy might arrive at the camp.

There are, however, some circumstances which render it indispensable that an encampment should be strengthened by fortifications; as when the troops are inexperienced or the army is deficient in cavalry; but chiefly when a position is occupied which it is of the utmost importance to hold, because the possession of it would be advantageous to the enemy. The latter may then be reduced to the alternative of attacking the encampment at a disadvantage, or of suffering a loss of valuable time in making the movements necessary to turn it. In these cases, every resource of the engineer in the construction of works and in obstructing the approaches should be put in practice for the purpose of augmenting the resistance which the army may be capable of making.

A continuous line of works may therefore be admissible for an army inferior to that of the enemy, provided the extent of the line be not so great as to prevent the intrenchments from being sufficiently manned in every part; but a camp so fortified would possess no advantages for an army which is strong enough to assume the offensive on a favourable occasion presenting itself; and it is evident that, in this case, it would be sufficient to construct merely a few redoubts in situations from whence a fire of artillery might be directed for the purpose of defending the approaches, while the disposable force of the army might be kept in masses ready, at a proper time, to make a movement to the front through the intervals between the works.

This principle does not, till lately, appear to have been well understood; and the cautious spirit with which a campaign was conducted during the 18th century contrasts strongly with the bold measures generally pursued in the wars of Napoleon. Marshal Daun, though always superior in number to the Prussians, intrenched himself with the utmost anxiety; and in 1759, when he took up a position near Dresden, though the King of Prussia had lost the battle of Kunersdorf, and the Austrian army was encamped upon steep rocks, covered by a stream difficult to pass, yet the marshal surrounded himself with works so numerous, that even the smallest paths were protected by them, and so strong, that twenty years afterwards they were in existence. But one of the most celebrated of these intrenched camps was that which, in 1761, the King of Prussia took up at Buntzelwitz, in order to cover Breslau. This camp was formed within a chain of hills protected on three sides by streams: six salient points on the contour were fortified by bastions, the fires from which would have flanked the intermediate parts of the line, and these were further protected by *flèches*, constituting a sort of broken curtain between every two redoubts. Nearly 180 pieces of artillery were planted to defend the avenues, and the camp was surrounded by abatis and other obstacles by which the approach of an enemy might be impeded. (Jomini, 'Traité des Grandes Operations Militaires,' tom. iv.) Such intrenchments, however, avail nothing when the army is not commanded by a man of great military genius. The French camp at Malplaquet, in 1709, is stated to have been fortified with a triple line, consisting of breastworks, hedges, and felled trees; it was forced, however, though with great loss, by the allies under the Duke of Marlborough.

It is remarkable that, during the war in Spain, which in general was distinguished by inattention to the means of strengthening the positions occupied by the troops, one of the finest examples of an intrenched camp was afforded in that which the British army occupied before Lisbon in 1810. This consisted of a double line of detached redoubts constructed on all the commanding points of ground, for the purpose of defending the four great roads and the accessible passes by which the enemy could approach to that city. The first line began at the mouth of the Zizandra on the Atlantic; it crowned the heights above Torres Vedras, and following the chain of Monte Graça, extended to the Tagus at Alhandra, its whole length being about 29 miles. The second was about six miles in the rear of the first; it began at the mouth of the S. Lorenzo, on the ocean, passed over the heights at Mafra, Montechique, and Bucellas, and reached the Tagus, at Quintella, its whole extent, in length, being about 24 miles. The weakest part seems to have been the valley of Calhandris, near the Tagus, on the exterior line; but this part was afterwards strengthened by a double row of abatis, besides breast-works of earth and thick stone walls. When the lines were completed, they consisted of 152 redoubts, armed, in all, with 534 pieces of ordnance, and required above 34,000 men for their garrisons. The disbursements for their construction amounted to nearly 100,000*l.* (Colonel Jones, 'Memoranda on the Lines about Lisbon,' p. 107.) [LINES OF INTRENCHMENT; MILITARY POSITIONS.]

ENCAUSTIC PAINTING (ἐγκαυστική, encaústike) is a kind of painting much in vogue among the ancients, in which by heating or burning in (as the Greek term implies), the colours were rendered permanent in all their original splendour. In speaking of encaustic painting, the use of wax as a vehicle is usually understood, though it is not implied in the term. Encaustic painting with wax and naphtha as vehicles was practised among the Egyptians, but as Sir Gardner Wilkinson observes ('Anc. Egyptians,' iii. 312), "the time when it was first known there is uncertain, nor can we conclude from a specimen of Greek time that the same was practised in the Pharaonic age." Among the Greeks it was practised from a very early period, but there has been much discussion among the learned as to the methods employed and the materials used by them. Pliny, in his 'Natural History' (xxxv. 39), gives a short account of the invention and nature of this art. He says, "Ceris pingere ac picturam inurere, quis primus excogitaverit non constat." But though he expressly says wax, some persons have imagined that by *ceris* he here means some composition different from wax, and capable of bearing the fire, and that *inurere* means to enamel. In a succeeding chapter (41) he says that there were anciently two modes of encaustic painting, "cera et in ebore, cestro, id est, viriculo, donec classes pingi coepere. Hoc tertium accessit, resolutis igni ceris, penecillo utendi." The two ancient kinds, "with wax and on ivory," seem to have been both executed by means of a "cestrum, that is, a graver." The use of a brush in encaustic painting was not introduced till ships began to be painted, "the wax being melted by fire." It has been found extremely difficult to explain these three processes in a satisfactory manner. Of the two most ancient kinds, the first appears to have resembled painting, at least in its results; the second to have been either merely applying on a small scale and in a more careful manner the coarser mode of encaustic painting on wood, or else what Sir Charles Eastlake describes as ('Materials for a Hist. of Painting in Oil,' p. 151) "a sort of intaglio filled in with tints." The third kind, with a brush, and melting the wax by fire, continued in use almost or quite to the revival of painting in the 15th century.

The Marchese Haus ('Pittura all' Encausto'), assuming, with Pliny, three kinds of encaustic painting, distinguishes as an essential point, whether the cestrum (style, or graving tool) or the pencil was employed in the execution. In the first mode, the wax was, he supposes, melted, mixed with as much earth colour finely powdered as it could imbibe, and then this was spread on wood, or on a wall, with a hot spatula. When it became cold, it was the ground, in which the designer cut the lines with a cold pointed tool (style, cestrum), and thus, properly speaking, it was not the painting but the wax ground that was burnt in, and the name encaustic was improperly given to the painting. But a more probable explanation is, that by means of a style the colours prepared with wax were laid on to the prepared ground of the panel, and then toned down and blended by a hot iron, the flat end of the cestrum being probably used for the purpose. But the final burning in, or inustion, as it is technically called, appears to have been an essential part of the process.

With regard to the second kind, encaustic painting on ivory, Professor Grund, of Florence, who has devoted much attention to encaustic painting, suggests ('Die Malerey der Griechen,' Dresden, 1811) that when the practice of drawing on hard wax had been brought to some degree of perfection, they proceeded to apply it on a small scale to ivory, which was at that time in the highest estimation. Ivory tablets were therefore covered with red or black wax, and the design cut in it with the style, the object being to use the clear and smooth surface of the ivory for the lines, that they might look the more beautiful. This therefore was nothing more than applying to ivory what had previously been done on wood, or walls. But the probability seems much greater that this second mode was a species of intaglio: "The outlines first drawn on waxed ivory (for the facility of correcting them where necessary) were afterwards engraved in the substance; and the finished and shadowed design was filled in with one or more colours; being ultimately covered with a wax varnish by the aid of heat. Works so produced must have resembled the *nielli*, or, on a small scale, the *sgraffiti* of the Italians, and were no doubt quite as excellent. . . . The heated instrument with which the wax tints were blended was called *rhabdion:* it was probably flat at one end (like the extremity of the stylus); its forms and sizes, indeed, may have been as varied as those of brushes now. The encaustic painter who used the rhabdion or cestrum (for the terms are employed sometimes indiscriminately) was provided with a box with compartments, in which the variously tinted cakes or sticks of wax colours were kept. The canterium was not necessary; the rhabdion, heated in a small furnace kept at hand, supplied its place." (Eastlake, pp. 149–54.)

The third kind is the applying the colours with the brush or pencil. With respect to the manner in which this was executed, opinions again differ. The received notion seems to be that the wax was dissolved, the colours mixed with it, and laid on with the pencil, and the painting then finished by careful approximation to the fire, whence this kind of painting became properly encaustic. For this purpose a hot iron, or a pan of coals (cauterium) was used. The painting was commonly executed on wood, but also on walls. The point on which there has been most difference of opinion among later writers who have treated of this third mode is, as to the means adopted for mixing the wax with the colours so as to allow of their being used with a brush. The modes suggested are resolvable into three: "1. The solution of wax by a lixivium, or in more general terms, by any means which will allow of the pigment being mixed with water. 2. The solution by means of heat in a fixed oil. 3. The solution by means of an essential oil." (Eastlake.) For all of these, certain authorities may be cited, but the last is that which on the whole appears to be the most feasible; and it accords most with modern practice and chemical analysis. Wilkinson, we have seen, states that in the encaustic painting of the ancient Egyptians wax and naphtha were found.

When painting had been greatly improved by the invention of the pencil, a new method of encaustic was attempted. Encaustic wax painting had hitherto been designing on a coloured ground: it now became painting with wax colours burnt in. When the artist had laid on the wax ground, and traced the outlines with the style, he proceeded to the colouring. From the wax mixed with the colours he separated with the hot style as much as he wanted to cover a certain space, and spread it over the ground, put a second, third, &c., colour next the first, so that he had local tint, half tint, and shade together, which he softened into each other with the hot style.

Encaustic painting did not come into use among the Greeks until after the time of Alexander, when the arts were beginning to decline. The works of all the greatest painters had been executed in tempera, and tempera painting therefore continued to be regarded as the higher branch of the art. For small works, however, encaustic was regarded as the superior method, and the small painted tablets of Pausias, and the portraits of the female painter Lala, of Cyzicum, were held in great estimation. But large pictures were also produced in encaustic, in Greece; and ceilings and walls were painted in encaustic. Among the Romans, encaustic painting, or at any rate painting with wax colours, was so general that ceræ came to be an ordinary term for painters' colours. Encaustic painting continued to be practised during the early centuries of Christianity, both in the Eastern and Western empire, almost to the exclusion of every other mode except mosaic; but eventually this last seems almost to have superseded it. Encaustic was not wholly abandoned, however, as late as the 14th century, though references to it in that and the previous centuries are extremely rare. Before its final extinction the practice of using a wax varnish with a final inustion appears to have been more prevalent than that of encaustic painting proper.

After the whole art of encaustic painting had long been lost, the memory of it was recovered by Count Caylus, in France, who announced to the Academy of Painting the method of painting in wax in 1752: a Mr. Bachelier however had actually painted a picture in wax in 1749, and is the author of a treatise on the art and secret of wax painting; and he was the first who communicated to the public the method of performing the operation of inustion, which chiefly characterises encaustic painting. The count kept his method secret for a time, and in 1754, exhibited at the Louvre a head of Minerva painted in the manner of the ancients. This was much admired, and it was affirmed that in wax painting the colours were more permanent, purer, and brighter than in oil painting: an account of his procedure was published in the 'Encyclopédie,' art. Encaustique. Several other persons made essays in this art, one of the most indefatigable being the Abate Vincenzo Requeno, who painted several works, and, in 1784, published a book on the subject, which was reprinted with additions at Parma, in 2 vols. 8vo. He was followed by painters and archæologists at Venice, Verona, Milan, and Rome, in each of which cities several works were executed in encaustic, and accounts of greater or less length and value published descriptive of the processes employed. After a time, the attempts proving unsatisfactory, the process fell into neglect, but some thirty years back it was again revived with considerable energy at Munich, under the patronage of the late king Ludwig, of Bavaria, and several public and private apartments were painted in it. The fashion spread to Berlin, Heidelberg, Vienna, and wherever the influence of the revived German school penetrated. It has also been followed to some extent in France; and many encaustic works have been executed of late years in various parts of Italy. The modes adopted by the painters of these countries have been very various, but in all wax has been the distinctive vehicle, and almost invariably the wax has been dissolved in turpentine or some other essential oil (at least for mural painting) and coarse mastic or other resin has been used for strengthening the vehicle with which the colours are laid on the wall. The final inustion is omitted in some of the processes. Notwithstanding the failure of many of the most promising works executed in it, the process has its admirers and advocates; and many still believe that, with some improvements in the methods hitherto adopted, it is capable of being rendered the most permanent, as well as the most brilliant, style of painting. But it is, perhaps, more fitted for decorative work than for painting of a higher order. The complexities of the manipulation must cramp the hand of the painter, and the firmness, decision, and sharpness of touch—that individuality of handling in fact—which are so great a charm in the work of a great painter, can hardly be attainable in a process the last stage of which removes all traces of the pencil. For decoration this artistic individuality is less required, and the warmth and glow of the colours, the shining surface, as well as the facility with which it can be cleaned, are greatly in its favour. The fullest account of the modern process, and that which judiciously carried out promises to be most successful, is that of M. J. P. de Montabert, 'Traité Complet de la Peinture,' vol. viii. p. 526, &c. The work of Sir C. L. Eastlake, quoted above, should also be referred to; and much of value on the history of the art, and on the ancient and modern processes, will be found in the following works, which, with those given above, will supply ample references if it be desired to carry the inquiry farther: Millin, 'Dictionnaire des Beaux Arts' (art. Encaustique); Durosiez, 'Manuel du Peintre à la Cire' (Par. 1844); Raoul Rochette, 'Peinture Inédites' (Par. 1836); Letronne, 'Lettres d'un Antiquaire à un Artiste' (Par. 1840); John, 'Die Malerei der Alten' (Berlin, 1836); Wiegmann, 'Die Malerei der Alten;' Müller, 'Archäologie der Kunst,' § 320; and Reports of Commissioners of Fine Arts.

ENCAUSTIC TILES AND PAVEMENTS. [TILES AND PAVEMENTS.]

ENCEINTE is the term applied in fortification to the works of the *body of the place*; or the first belt, or line of ramparts (generally continuous), which surround the place.

ENCKE'S COMET. [COMETS.]

ENCYCLOPÆDIA; ENCYCLOPÉDIE. [DICTIONARY.]

ENDECAGON, a figure of eleven sides.

ENDEMIC (*ἔνδημος, endémus*, from *ἐν*, in or among; and *δῆμος*, people, that which is among a people). By this word are expressed those peculiar forms of disease which arise spontaneously, as it is termed, in a country or in particular localities, and which are ordinarily produced by the peculiar climate, soil, air, water, &c. Thus, ague is the endemic disease of marshy countries or localities; the swelled throat or bronchocele is endemic in the Alps, and the plica in Poland. The word bears pretty much the same signification in relation to the diseases of a country that the term indigenous does to its plants. It is used in contradistinction to *epidemic*. [EPIDEMIC.]

ENDOCARDITIS. [HEART, DISEASES OF.]

ENDORSEMENT. [BILL OF EXCHANGE.]

ENDOSMOSE is the attraction through an animal or vegetable membrane of thin fluid by a denser fluid. M. Dutrochet found that if he filled the swimming bladder of a carp with thin mucilage and placed it in water, the bladder gained weight by attracting water through its sides: to this phenomenon he gave the name of *Endosmose* (from *ἔνδον* and *ὠσμος*). He also found that if he filled the same bladder with water and placed it in thin mucilage, it lost weight, its contents being partially attracted through its sides into the surrounding mucilage; this counter phenomenon he named *Exosmose* (from *ἐξ* and *ὠσμος*). The same circumstances were seen to occur in the transmission of fluids through the tissue of plants; it was found possible to gorge parts of vegetables with fluid by merely placing them in water, and to empty them again by rendering the fluid in which they were placed more dense than that which they contained. It was also ascertained that this phenomenon took place with considerable force: Dutrochet says that water thickened with sugar in the proportion of 1 part sugar to 2 parts water, was productive of a power of endosmose capable of sustaining a column of mercury of 127 inches, or the weight of 4½ atmospheres.

This phenomenon is by its discoverer considered sufficient to explain many of the movements of the fluids both of plants and animals; his first book upon the subject is entitled 'L'Agent immédiat du Mouvement Vital, dévoilé dans sa nature et dans son mode d'action chez les Végétaux et chez les Animaux,' Paris, 1826, and in his numerous more recent writings he sustains the same opinion. To the effects of endosmose he refers the motion of sap; the sleep of leaves; the various directions taken by plants under the influence of external agents, such as turning to the light or away from it; many kinds of irritability; the attraction of fluids to particular points, and the like. That Dutrochet's arguments are extremely ingenious, and his observations highly curious, no one will deny; but we agree with De Candolle, that, supposing this celebrated physiologist's views to be correct, we must still have recourse to vital force as the great and inexplicable cause of all such phenomena. When organic tissue dies, it does not lose its mere hygrometrical powers, nor do its tubes cease to exert their capillarity, but no more vital movement of fluids takes place; yet mere endosmose will take effect through dead membranes, as is proved by the instrument called an *endosmometer*. [OSMOMETER] We can only then allow endosmose to be one of the powers which, in combination with vital force, assist in producing some of the phenomena of life.

Dutrochet considers endosmose to be owing to what he calls *inter-capillary electricity*, grounding his opinion partly upon the experiment of Porret, who found that when two liquids of different levels are separated by a membrane, they may be brought to a level by establishing an electrical current between the two, thus rendering the membrane permeable; and partly upon experiments of his own. But M. Poisson, on the contrary, has demonstrated that endosmose may be the result of capillary attraction joined to differences in the affinity of heterogeneous substances. ('Ann. de Chim.,' vol. 35, p. 98.)

The more recent development of this subject will be given under OSMOSE, to which we referred under CAPILLARY ATTRACTION; but we may here remark, that the phenomena of endosmosis and exosmosis, are intimately connected with the process of liquid diffusion. [DIFFUSION.]

ENDOWMENT. [DOWER; VICARAGE.]

ENEMATA. [CLYSTERS.]

ENFEOFFMENT. [FEOFFMENT.]

ENFILADE is the term applied to a fire of artillery or musketry when made in the direction of the length of an enemy's line of troops, or when made from any battery to the interior of an enemy's rampart or trench in the direction of its length. When an artillery fire is so employed by the besiegers of a fortress, the intention is to dismount the guns of the defenders; and this end it accomplishes with more certainty than if the fire were directed from the front towards the mouths of the embrasures, both because the side of a gun-carriage presents a larger surface than the muzzle of the piece to the action of the shot, and because the same shot may take effect against two or more guns placed upon the same line of rampart, or sweeping along the whole length of parapet, though missing one gun may take effect on another. An enfilading fire of artillery is also used by the besiegers to destroy the palisades or other obstacles behind a glacis, and to prevent the defenders from remaining at their parapets. When employed by the defenders of a fortress, it is intended to sweep any of the besiegers' trenches which may from necessity, or through the fault of the engineer, lie in a direction tending towards some part of the ramparts of the fortress.

The destructive effects of an enfilading fire, when directed against the guns on a rampart, are diminished by constructing traverses across the rampart at intervals, or by placing the guns in blindages. And, to avoid such fire in the trenches of the besiegers, the practice is to form those trenches in zig-zag directions, tending alternately to the right and left of the general line of the approaches, so that, if produced, they may fall on the exterior of all the ramparts from whence a fire might be directed towards the approaches: when this is not possible it becomes necessary to raise traverses in such trenches as are thus exposed to the fire.

In Sir John T. Jones's Journals of the Sieges in Spain, there is given an account of the ingenious attempt made by a French corporal to cause one of the trenches of the besiegers before Badajos to be enfiladed by the guns of the fortress: the man contrived secretly in the evening to displace on the ground the tracing cord which the British engineer had stretched in order to indicate the intended direction of the trench; and the attempt only failed because the officer who came on duty for the night accidentally discovered, before darkness came on, the error in the position of the line. [RICOCHET.]

ENFRANCHISEMENT. [COPYHOLD.]

ENGINEERING (from the French word *ingénieur*) is properly the art of constructing and using engines or machines; but the term is also applied to that of executing such works as are the objects of civil and military architecture, in which machinery is in general extensively employed.

A distinction has long been made between the civil and military engineer; and since everything relating to the service of artillery is now confided to a particular corps, the duty of the military engineer may be said to comprehend the construction of fortifications, both permanent and temporary, including the trenches and batteries required in besieging places; also of barracks, magazines, and other works connected with warlike affairs.

Of the military engineer it may be said that a greater knowledge of the more minute details of construction is required than would suffice in the civil practitioner; because it may happen that the former is called upon to exercise his profession in some colony where workmen adequately skilled in the mechanical operations may be wanting. The accomplishment of the work may then become impossible, should the officer not be qualified to give the necessary instructions to those who are placed under his direction.

ENGINEERING, CIVIL, comprehends the designing and execution of every great work by which commerce and the practice of the useful arts may be facilitated, provided it be not of an artistic or ornamental character. Thus, in creating or improving the communications of a country, the civil engineer would be called upon to form a road through hills or over valleys or rivers, or to excavate a canal in connection with the waters by which it may be supplied, and to build the locks for retaining the surface of the water at different levels, in different places, when the inequalities of the ground are considerable. He raises embankments to resist the encroachments of the sea or to reclaim the land which it may have covered, and breakwaters to break the force of the waves at the mouths of natural harbours. He renders rivers navigable when their course is obstructed by rocks or banks; he forms docks or artificial harbours where ships may remain in security: he executes the works required for the water supply, the draining and lighting of towns, or the drainage and irrigation of the country districts, and he is required to penetrate by mines to vast depths for the purpose of seeking the mineral treasures contained within the bosom of the earth. Such are the occupations of this important class of men; and it is necessary to observe that they frequently, in addition, practise the avocation of the machinist in executing the presses, mills, looms, and other great machines employed in the arts and manufactures; and particularly in constructing steam engines and the apparatus by which they are rendered available for giving motion to ships, carriages, or machinery.

In France the title of engineer is extended to persons who are employed for the public service in trigonometrical surveying in the interior of a country or on the coasts, and in the practice of naval architecture. The French have thus a corps of ingénieurs géographes, of ingénieurs d'hydrographie, and of ingénieurs de marine.

Engineering must have originated with the first application of a lever for the purpose of moving a mass of any material which exerted a resistance exceeding the unassisted strength of man: by observing the effects produced in operations of that nature, the laws of the action of bodies on one another were gradually discovered, and mechanics, the science of the engineer, arose.

Archimedes, in addition to the title of geometer, may with justice claim that of mechanician and engineer; and in fact he is the first person who is known to have applied himself to the cultivation of the mixed mathematical sciences. Besides demonstrating the fundamental property of the lever, he determined the centre of gravity in bodies of certain forms, and the positions in which bodies remain in equilibrio in a fluid; and from the celebrity he acquired among the ancients by the mechanical contrivances which, according to Polybius, he put in practice for the defence of Syracuse, we may conclude that if those contrivances were not his own inventions, they must have contained improvements upon such as had been in use before his time.

Vitruvius wrote his treatise on architecture during the reign, as it is generally believed, of Augustus. In that treatise he describes the manner of building the walls and towers for fortifying towns, the construction of temples, basilicas, theatres, and private dwellings; he describes the principal military engines which were then in use; he also gives some account of machines for drawing and raising weights, of engines for raising water, and of mills turned by water for grinding corn. The work may therefore be considered as comprehending every important object connected with engineering at the time in which he lived. Now he states, in the proem to the first book, that he had been appointed by the emperor to have the charge of the warlike engines; and in another place, that he had designed and executed a basilica at Fanum; it is evident therefore that he united in his person the character of engineer and architect; and among the ancients the profession of the former seems to have been generally included in that of the latter. The 'machinarius' was probably the artificer, or the officer who superintended the civil and military machines at the siege of a fortress.

Of the national works executed by the ancients, and which are to be considered as properly falling within the province of the engineer, some of the first of which we have any intimation are the sewerage of Nimroud lately discovered by Messrs. Botta and Flandin; and the canal uniting the Red Sea and the Nile, which, according to Pliny, was begun by Sesostris, or, according to Herodotus, by Necos, the son of Psammetichus, and finished by Darius the First. The canal of Xerxes across the isthmus of the peninsula of Athos is another example of works of this kind. The introduction of arches in works of magnitude may be said to have constituted an epoch in the profession of the architectural engineer, as the idea of giving to blocks of stone a form which would enable them to sustain themselves in balanced rest by their mutual pressures, the discovery of the means of arranging them on a curve surface, and the determination of the magnitudes of the piers or abutments so that the lateral pressure of the vault might be adequately resisted, imply a higher degree of intellectual power than is exhibited in covering a space with a horizontal roof. The Cloaca Maxima at Rome is probably the most ancient example in Europe of this scientific construction; the dome of the Pantheon, and the various arches of the Thermæ and of other public buildings both at Rome and in the provinces, such as aqueducts, and bridges, attest the grandeur of the design, combined with purposes of public utility, which characterised the works of the engineers and architects who lived under the early emperors.

Vitruvius enumerates several Greeks who had written on machinery; but from his time to that in which Italy rose again to importance after the fall of the empire, little is known concerning the state of engineering in Europe. Subsequently to the last-mentioned epoch, Carden, Guido Ubaldi, Valerius, and Galileo, in that country, and Stevinus, Huygens, and Descartes, in the north, are distinguished as cultivators of theoretical mechanics. Galileo particularly deserves to be named for his discovery of the laws of motion, his application of the pendulum to the measurement of time, for his theory of projectiles, and his contributions to the science of hydraulics as applied to engineering. From that time almost every distinguished mathematician, both on the continent and in this country, has contributed to the advancement of the mechanical sciences.

Previous to the commencement of the 18th century the most celebrated practical engineers were Brunelleschi, who built the dome of St. Mary at Florence; Peruzzi, San Gallo, and Michel Angelo, who executed that of St. Peter at Rome; Leonardo da Vinci, who constructed the earliest canal-lock in Europe; San Michæli, the supposed inventor of the bastion system of fortification: and Sir Christopher Wren, the architect of St. Paul's Cathedral.

In Holland and in the north of Italy the necessity of securing the low grounds against the inundations of the seas and rivers, and of obtaining an inland navigation for the purposes of commerce, gave rise to the cultivation of that branch of engineering which relates to hydraulic constructions; and the invention of the lock for canals is sometimes said to have taken place in the latter country about the middle of the 13th century. Indeed we find the profession practised in those countries on an extensive scale when there was not a man in England capable of undertaking the formation of a canal to drain the ground. Before the reign of Charles I. it appears to have been the practice to send to Holland for an engineer when any work of that nature was to be undertaken.

But the extension of the manufactures of this country soon after that period, and the consequent augmentation both of its internal and foreign commerce, called forth all the energies of its inhabitants, who, at length, in the works performed for facilitating the means of communicating between one place and another, and in the practice of the useful arts, rose to an eminence which other nations have not been able to surpass. Among the former may be mentioned the numerous canals and railways which intersect the country; the majestic bridges executed in stone over the Thames; in cast-iron over the Avon, the Thames, &c.; and those on the suspension principle at the Menai and at Hammersmith. Among the men in this branch of engineering to whom the nation is indebted are Brindley, Smeaton, Jessop, Telford, the Rennies, the Brunels, and the Stephensons.

The invention of the steam-engine, or rather its improvements in 1769, opened a new field for the talent of the engineer in the numerous uses to which the machine became applicable. Before the time of Watt it had been employed only as a pump to raise water; but this mechanician, by converting the reciprocating motion of the beam into a rotatory motion, rendered it capable, not only of replacing with greatly augmented energy, the power of wind, water, or horses, in giving motion to machinery for the purposes required in the arts, but also of serving as a first mover for propelling vessels through water, or for drawing carriages over land.

The course of education by which a student may qualify himself to become an engineer, whether civil or military, must necessarily comprehend a greater extent both of the pure and physical sciences than would be required for a person who is to follow any other profession. It will be, perhaps for ever, a matter of question how much mathematics should enter into a school course of engineering, and there are, no doubt, some persons who contend that no more is required than would serve to compute the cost of materials and the wages of labour: this, and the observation of existing examples, being supposed by such persons to be sufficient to enable a man to enter upon the practice of the profession. It is not, however, with such a limited knowledge that an engineer can be qualified to design an important work, which it may be required to conduct under new and difficult circumstances. Mere science certainly cannot make a man an engineer; for analytical formulæ relating to mechanical equilibrium being necessarily founded on the erroneous assumption that materials are perfectly hard, perfectly smooth, &c., and that the actions of bodies on one another are subject to invariable laws, have no practical utility unless corrected by observation and experiment. On the other hand, mere diligence in observing the results of practical operations will never raise a man to proficiency in the art unless he be gifted with very extraordinary powers. A judicious combination of theory and practice is indispensable, and such a combination can only be made by a man in whom great natural talent is blended with all the aids that the sciences can afford.

Of the military engineer it may be said that a greater knowledge of the more minute and mechanical details of construction is required than would suffice for the civil practitioner; because it may happen that the former is called upon to exercise his profession in some colony where workmen adequately skilled in the mechanical operations may be wanting. The accomplishment of the work may then become impossible, should the officer not be qualified to give the necessary instructions to those who are placed under his direction.

The professions of an architect and of an engineer, as they are practised at present, may be said to coincide with one another to a certain extent. The members of both of them must be able to form a judgment of the quality of the ground in which the foundations of their buildings are to be laid; they must be acquainted with the capacities of different materials, wood, stone, and iron, for resisting the strains to which such materials may be exposed, so that sufficient strength may be obtained with a due attention to economy; and they must equally attend to the princples of equilibrium in their roofs, arches, and domes, arranging the beams, bars, or voussoirs so that they may remain at rest with as little strain as possible upon the connecting ties by which the joints are strengthened. But here the two professions diverge from one another; for whilst the engineer has to determine, by a process of levelling, the profile of the ground on perhaps an extensive line of country, for a road or a canal; or has to determine the forms and dimensions of his retaining walls, so that they may resist the pressure of earth or water against them; or, finally, to devise methods of rendering the action of his moving powers uniform, and of transmitting them through a train of machinery to the place where the effect is to be produced,—the architect is engaged in designing the external forms and internal arrangements of edifices, in which, whether intended as palaces or private dwellings, or as buildings consecrated to the service of religion or of the state, architectonic beauty must be combined with fitness for the purposes for which they are intended.

ENGLISH BLUE. [COPPER, CARBONATE OF.]

ENGLISH RED. [COLOURING MATTERS.]

ENGRAVING, the art of executing designs by incision upon plates of copper, steel, or other metal, or in relief upon wood, for the purpose of obtaining therefrom impressions or prints upon paper. Although, in this sense of the term, the art is only coeval with that of printing, it has been practised with a more limited object from the earliest periods on record, in a similar manner and with similar instruments to those used at the present time. Except incidentally, however, we shall confine our attention in the present article to incised engraving on metal plates. Engraving on wood; on gems; and of dies for coins and medals will be treated under separate articles. [Wood Engraving; Cameo; Intaglio; Coins; Die-Sinking; Medals.]

On referring to sacred history we find in the writings of Moses rather detailed accounts of the character of the engraved works executed in his time, and of the substances whereon they were wrought; nor are we left in ignorance even of the names of the practising artists among the Israelites. Thus from the book of Exodus we learn that when Moses had liberated the Jews from Egyptian bondage, he was commanded to "make a plate of pure gold, and grave upon it, like the engravings of a signet, holiness to the Lord." He was also commanded "to take two onyx stones, and grave on them the names of the children of Israel according to their birth, with the work of an engraver on stone, like the engravings of a signet." Both these passages distinctly imply the practice of gem and seal engraving, and also of engraving on metal plates, a knowledge of which, among other arts, was, without doubt, acquired by the Israelites during their captivity in Egypt; and specimens of the art as practised in that nation, perhaps at as early a period as that now under notice, still exist. In the book of Exodus also honourable mention is made of one Bezaleel, who appears to have united the callings of the engraver, the jeweller, and the lapidary; and it is said that he "was filled with wisdom of heart to work all manner of work with the graver, as well as to devise cunning works; to work in gold, and in silver, and in brass, and in cutting of stones to set them." "And it was put into his heart that both he and Aholiab might teach them that were filled with wisdom to work all manner of work of the engraver." These are selected from numerous other passages in Scripture as sufficiently attesting the practice of several branches of engraving at this early period: from the same source indeed we learn that some of them, as for example, the engraving of signets, was practised at a time anterior to that of Moses.

The hieroglyphics and other remains of Egyptian incised work are the most ancient examples of the art existing, and among the most ancient relics of early civilisation now extant. The British Museum is particularly rich in such specimens, some of which are engraved on metal, and have been chiefly found in the coffins or cases of mummies. These engravings of hieroglyphics on metal, as well as those on the ancient sarcophagi, are evidently executed with similar instruments to those now in use: some of the lines narrowing downwards have clearly been cut with the lozenge-shaped graver now chiefly used; but other lines, being of the same width through their whole depth, must have been produced with that species of graver called a scooper, still used for effecting broad incisions. Only a single step indeed was needed for the Egyptians to have made the discovery of engraving in the sense of the definition at the head of this article. They used colours for various purposes, and they made paper, but the idea of filling the incisions in their metal plates with colour and taking off an impression on paper never occurred to them; nor did it occur to any other people for more than 3000 years later. That only this single step was required has been shown by the fact of impressions being actually taken on paper from these Egyptian engravings: among others from one of the very oldest in the British Museum, a plate found in a mummy chest by Dr. Mead. Like the Egyptians, the ancient Assyrians engraved both on stone and metal; they even went so far as to take impressions from their incised slabs, but it was in clay instead of on paper, and simply in relief, and not by means of ink or any coloured vehicle.

From Herodotus (v. 49) we learn that one of the earliest uses to which engraving was applied among the Greeks was the delineation of maps on metal plates. He says that "Aristagoras appeared before the king of Sparta with a tablet of brass in his hand, on which was inscribed every part of the habitable world, the seas, and the rivers; and to this he pointed as he spoke of the several countries between the Ionian Sea and Susa." The date of this event was 500 B.C. The engraving of metals with incised patterns for ornamental purposes was also much practised by the Greeks. Among the Etruscans, incised work was much in vogue from a very remote period; and prints which have been taken from Etruscan mirrors, of which there are several in the British Museum, sufficiently attest the capacity of these early engravings to deliver impressions.

In the peninsula of India, also, the art of engraving on plates of copper appears to have been practised long before the Christian era. It would appear that it was there customary to ratify grants of land by deeds of transfer actually engraven on plates of copper, as we now write them on skins of parchment. A copy of one of these very interesting relics is given with an English translation by Mr. Wilkins, in the first volume of the 'Asiatic Researches,' page 123. It is in the Sanscrit language, and bears date twenty years before the birth of Christ. Engraving was probably practised by the Chinese at a still earlier period. It would, however, be idle to follow further among the ancients a process that may in fact be said to have prevailed in every country where civilisation had made any progress.

After the fall of the Roman empire incised engraving on metal plates continued to be pursued by Byzantine artists; and throughout the middle ages the art was practised in Italy, Germany, and other parts of Europe. Ecclesiastical instruments of various kinds, weapons, and articles of personal ornament and household use, of mediæval date with engraved designs, often of admirable execution, are found in almost every public museum, and in numerous private collections. The metal sepulchral slabs, or brasses as they are termed [Brasses], of France and the Netherlands, and once so general in our own churches, were executed entirely with the graver, and in precisely the same manner that a copper-plate is now engraved which is intended to be printed from; but as they were commonly exposed to the feet of the congregation, the strokes were cut deep that they might endure the longer, and consequently very neat workmanship is not to be expected. Some of them, however, especially those of the 13th and 14th centuries, bear evidence of considerable ability in the workmen.

We now approach the period when the invention of *printing* gave to engraving a new direction, and produced an effect on the civilisation of the world as astonishing as it is incalculable. The chief obstacle to printing had already been removed by the manufacture of paper from linen rags, which had become generally known in Europe at the latter end of the 14th century. It must be remembered, as giving additional interest to this subject, that it is to a certain class of engravers that we are immediately indebted for the first printed books, which were actually impressed from engraved wooden tablets—a method which was afterwards improved by substituting movable metal types; and thus the arts of engraving and printing, at the same time that they constitute the sole means by which all kinds of knowledge may be extensively diffused, have placed it within the power of all to possess the thoughts of the best men in literature, science, and art.

The first prints, as we have already intimated, were obtained from engraved wood blocks. This might naturally be expected, because the process of printing from such works is so simple and obvious, not requiring even a press, that persons of reflection are astonished, not that printing was invented so soon, but that it had not been discovered sooner. To obtain impressions from the incised hollows of an engraved metal plate, on the contrary, is a much less obvious process, requiring the aid of a somewhat complicated machine, called a rolling-press. We need not wonder, therefore, that its discovery should have been later; and, indeed, the two processes are so very different, that when one was discovered it did not lead necessarily to the other.

The earliest print with a date attached to it is one known as the St. Christopher, which is from a wood block, and dated 1423; but no impression from an engraved *plate* has been found with a date for many years later. It has long been a disputed question whether the art of engraving on metal plates for taking impressions on paper originated in Italy or Germany. According to Vasari, it originated from a discovery made by Maso Finneguerra, a Florentine goldsmith and worker in niello, about the year 1450; and this is the view commonly adopted by English, though contested by German, writers. Be that as it may, there has never existed a doubt that the art had its origin in the workshops of the goldsmiths about the middle of the 15th century. Many of these goldsmiths were *niellatori*, or workers in *niello*,—a mode of ornamental engraving usually performed on silver plates, the design engraved on which was afterwards filled in with a black composition, which from its colour was called by the ancients *nigellum*, a word curtailed by the Italians into *niello*. [Niello.] This being run into the engraved lines, produced the effect of shadow, and had very much the appearance of a print. It was usual with the artists who worked in niello to ascertain the appearance of their work at different stages of its progress by taking casts in soft earth of the portions executed. Upon these casts they poured melted sulphur, and thus obtained a fac-simile of their engraving. Then, by rubbing a mixture of lamp-black and oil into the design on the sulphur, they were able to judge what would be the effect of the work previous to inlaying with the nigellum or mixture of silver and lead. According to Vasari and the Italian writers, it occurred to Finneguerra to try if the same result would follow on a piece of moistened paper if laid over the design thus filled with ink and pressed by a roller. The experiment succeeded; and the consequence was the gradual improvement of the new art both in his hands and those of Baccio Baldini, Sandro Botticelli, Antonio Pollajuoli, and Andrea Mantegna, to whom he communicated the process.

Examples of these sulphur-casts from nielli (or "sulphurs," as they are technically designated) still exist in the museums of the Continent and also in the British Museum. In the British Museum is one of great interest in the history of the art of engraving, it having been taken from a niello in Maso Finneguerra's famous Pax, executed by direction of the Guild of Merchants of Florence for the Baptistery of that city, and now in the Florence Museum. But the Imperial Collection in Paris possesses an impression printed on paper from the silver plate of this very Pax, prior to the insertion of the niello. Now it appears from the great book of the Mercatanti of Florence, cited by Gaye ('Carteggio inedito d'artisti dei secoli 14, 15, 16.' 8vo, Firenze, 1839, i. p. 112), that this Pax was executed in 1450, and hence it has been supposed, from that year being given as the date of the discovery, and from there existing both a sulphur and an impression on paper, that this is the very plate upon which the experiment was first tried. At any rate, it has been regarded as having "established the claim of the Italians to the discovery of taking off impressions on paper from incised metal plates."

Herr J. D. Passavant, however, in a work recently issued ('Le Peintre-Graveur,' Leipzic, 1860), seems once more to have restored the discovery to the Germans. There are, he asserts (p. 192), in the cabinets of Dresden and Munich proofs from nielli executed by German engravers, which leave little reason to doubt that the process of taking impressions on paper from engraved plates was practised in Germany about 1440. But Herr Passavant calls attention to some recently-discovered prints from plates engraved for the purpose of supplying impressions on paper, of an earlier date than the impression from Finneguerra's niello, and others earlier than any known Italian print. The first series consists of a set of seven prints of the 'Passion,' in the possession of M. Renouvier of Montpellier. Only one of them is dated. It represents the 'Flagellation of Our Saviour,' and is inscribed 1446: the execution is rude and archaic; the contours are strongly marked; and the slight indications of shadows are expressed by hatchings, short and irregular in the flesh and the architectural details, but longer in the draperies. A very superior style is exhibited in a print (in the collection of Herr T. O. Weigel of Leipzic) of the 'Immaculate Virgin,' which bears the date 1451. Next in order of antiquity is a series of 27 subjects from the 'Life of Christ,' now in the British Museum, of which 'The Last Supper' is dated 1457. These are the oldest impressions known from engravings properly so called, and (with at least one other dated 1458) they are all earlier than the first Italian prints known, which are those of Baccio Baldini, and are believed to have been executed in 1460.

As regards the first of these prints, there can be no doubt that, if Herr Passavant's description be correct, it is of a much earlier date than the earliest known Italian engraving. Of the second we have some doubt. A fac-simile of it was published in Naumann's 'Archiv.' for 1858, and if that is really a fac-simile it wears a very questionable appearance. The drawing is not only, as Passavant observes, "refined, and founded upon a nice observation of nature," and has "a certain feeling of beauty," but the delicacy and the beauty have a much more modern air than is at all usual in prints of a later date—those of Martin Schöngauer, for instance. We should hardly think it possible Passavant could be deceived as to the genuineness of the print, were he not a German, and likely to look at it therefore with somewhat of national prepossession. On the other hand, the fac-similist may not have copied faithfully, and it is on the side of modern refinement he would be likely to err. As to his third example, we believe (though he does not say so) that he has not seen these prints of the Passion in the British Museum collection. Probably he has obtained his knowledge of them from Waagen, who, in his supplementary volume ('Galleries of Art, &c., in Great Britain,' iv. 49), speaks of them as engravings from metal plates. It is by no means certain, however, that they are printed from metal plates. At the Museum they are placed among the early German wood engravings. They are in fact little more than outlines, and they have been so fully coloured that the ink is for the most part hidden. At the best, from the mode then adopted for printing from wood blocks, it is often very difficult, if not almost impossible, to determine whether a print is a woodcut or a copper-plate engraving; and in this instance it is not only rendered more than usually difficult by their being coloured, but the difficulty is increased by their being printed on vellum, so that no help can be got from examining the back of the print. On the whole then we are disposed to place most reliance on the oldest of these three prints, and if that be authentic it is of course sufficient to sustain the priority of the Germans.

Passavant, indeed, endeavours to show that the Italians acquired the art from the German artists, who are known to have been in the habit of visiting Italy at that time, and an imitation of whose manner of working, he says, is easily traceable in the prints of the early Italian engravers. It hardly seems necessary to resort to such an hypothesis, since the Italians were not only excellent artists, but singularly expert workers in niello; and the engraving of plates for printing would require very little modification of the process to which they were accustomed. In the British Museum however may be seen a couple of prints (of the existence of which Passavant takes no notice), which show that the early Italian engravers were accustomed to look to Germany for the materials of their art. The oldest of these two prints is by the German master of 1466, and is known as 'Our Lady of Einsidlen.' The other is an anonymous Italian print of a 'Youth in Armour,' and is of the latter half of the 15th century. But the remarkable circumstance about them is that both have been executed on the same plate of metal, as Mr. Carpenter (the keeper of the drawings and engravings) discovered when arranging the early Italian and German collections. The earlier engraving of the Master of 1466 had of course been erased to make way for the Italian engraving; but so imperfectly was the erasure made, that portions of the inscription are plainly visible on a careful examination of the surface of the later print. These two engravings, with an admirable selection of rare and choice specimens of the Italian and German engravers of the 15th to the 17th centuries, and also several nielli, and casts and paper impressions from them, are exhibited to the public in the centre of the King's Library. The collection of engravings at the British Museum, we may add, is exceedingly rich in early works, and in the choicest productions of the best engravers; and the collection is admirably arranged: the portion exhibited is but a sample of the treasures stored up in the Print Room.

Our limits will not allow us to dwell on the merits or performances of those early masters, contemporaries of Finneguerra, to whose exertions we are nevertheless much indebted for the rapid approaches of the art towards excellence. Of these, Baldini, Botticelli, and Andrea Mantegna, have already been named among the Italians; while among the Germans, copper-plate engraving was very early and very greatly improved by Martin Schöngauer, Israel Van Mecheln, Leydenwurf, Wolgemuth, &c. The success of the early German engravers is not surprising when we recollect that wood engraving had been first practised in that country forty years earlier, and consequently that they had anticipated the Italians in a knowledge of printing-ink and the press; nay, it is remarkable that the first *book* printed at *Rome* (an edition of Ptolemy's Geography) was also illustrated by the first *plate engravings*, twenty-seven in number, which were maps, and were executed there by two Germans, Sweynheym and Buckink; the latter completing what the former left unfinished at his death. This work is dated 1478, but was commenced in 1472.

One of the first books illustrated with designs on engraved plates was indeed the production of Italian artists; this was the work called 'Il Monte Sancto di Dio,' published at Florence in 1477, and illustrated with engravings by Baccio Baldini, ('Bartsch, Peintre-Gravure, vol. 13, p. 189). An edition of Dante's 'Inferno,' published at Florence in 1481, was also embellished with engravings by Baccio Baldini, after the designs of Botticelli. It is worthy of remark that these plates were not printed on the same paper as the letter-press, but blank spaces were left at the head of each canto, over which the prints were pasted.

Omitting farther notice of those early masters who flourished at the end of the 15th, we shall pass on to the 16th century, at the commencement of which the art was carried to a very high degree of excellence; in Italy by Marc Antonio Raimondi, and simultaneously by Albert Dürer in Germany, and Lucas Van Leyden in Holland: a constellation of talent, the appearance of which marks the most memorable epoch in the history of engraving. The great merit of Marc Antonio lay in the correctness and beauty of his outline: so great is his excellence in this respect, that it is believed that Raphael himself assisted him with his own hand on the copper. The character of his heads is admirably preserved, and the extremities marked with the truest precision; but his lights are not enriched with that variety of fainter tones which indicate local colour, nor do his prints possess the harmony arising from the chiaroscuro or the beauty of reflex light. [RAIMONDI, MARC ANTONIO, IN BIOG. DIV.]

Our space will not allow even a list of the engravers and painters who engraved or etched (a mode of engraving hereafter to be described) who flourished in Italy during the two centuries which succeeded the death of Marc Antonio: the principal of these however were Agostino de Musis, Marc de Ravenna, Caraglio, Giulio Bonasoni, and Enea Vico, all pupils of Marc Antonio; Georgio Ghisi of Mantua and his relatives Diana and Adam Ghisi, Cornelius Cort, &c. &c. But although by these and others the executive part of the art was continually though slowly improved, their powers in design or drawing, (in which the chief excellence of the school at all times consisted) declined, at least as fast as they advanced in mechanical skill, until at length in the 18th century the intellectual and mechanical excellences of the art were united in the works of Jacomo Frey; and from that time the credit of engraving in Italy has been well maintained by succeeding artists. The names of the principal painters who have practised engraving in Italy are Agostino Carracci, Stephano della Bella, Spagnoletto, Guercino, Salvator Rosa, Claude Lorraine, Swaneveldt, Canaletti, Piranesi, &c. &c.

In Germany engraving made more rapid strides towards excellence, in the mechanical parts of it; and at the commencement of the 16th century appeared Albert Dürer, a man whose universality of talent extended the boundaries of every department of art, and carried all to a degree of perfection previously unknown in that country. In all that relates to the executive part of the art of engraving the works of Albert Dürer deserve the highest praise. He carried his plates indeed to a much higher degree of finish than his Italian contemporaries, as his print of 'St. Jerome in the Room,' as it is called, the execution of which has scarcely ever been exceeded, will sufficiently attest. To his other honours has been added that of being the inventor of etching by corrosion, an art which has contributed most powerfully to the perfection of engraving. This, however, is at least doubtful, as there are prints in the British Museum (including one referred to by Passavant, which we have ourselves examined) and in other collections, of an earlier date than those of Dürer, which have all the appearance of having been etched. The practice of engraving by erosion with an acid was widely practised centuries earlier, and there can be little doubt that its obvious utility would soon lead the engravers of plates for printing to experiment upon its capabilities. But if not the discoverer Dürer was one of the earliest practitioners of the art; some of the most celebrated etchings from his hand being the prints of 'Christ praying on the Mount,' 1515; the 'Rape of Proserpine,' 1516; and the 'Cannon Landscape,' 1518. All these were evidently performed in the very infancy of the art, before the discovery of stopping out, as it is called, an expression which will be intelligible to the reader on a reference to our account of the process of etching. On examining the etchings of Albert Dürer, we see that they have all been corroded at one biting in; which sufficiently explains their monotonous appearance, and proves that stopping out was not understood, or it would have been had recourse to, as its advantages could not have been overlooked. It is most probable that the defective and monotonous tone occasioned by the want of this knowledge is the reason that so few corroded etchings were executed by Albert Dürer, who must have been otherwise fascinated by the facilities which this mode of engraving offered; as it is, his corroded etchings are much inferior to his other works, both on copper and wood. [Dürer, Albert, in Biog. Div.]

The principal German engravers, after Albert Dürer, are his pupil, Henry Aldegraver, together with Bartholomew and Hans Sebald Beham, Albert Altdorfer, James Bink, George Penz, Virgil Solis, &c. But the history of pure German art is very short, for most of these German engravers travelled into Italy for improvement, attracted by the fame of Marc Antonio; several of them are indeed his reputed disciples; and the consequence is, that the two schools may be said to have immediately, in some measure, blended; as under the influence of Italian taste the peculiar characteristics of German art in a great measure disappeared. From the small size of the majority of the works produced by these German engravers, they are generally distinguished as the "little masters," although many large plates were executed by them.

Lucas Jacobs, best known by the name of Lucas Van Leyden, was the father of the Dutch and Flemish schools, and the contemporary and friend of Albert Dürer, whose defects he fully possessed, while he fell short of his excellences. After Lucas Van Leyden the art was maintained in the Low Countries by the Wierinxes, the Sadelers, whose works are multifarious, and embrace every class of subject; the elder and younger Jode; Cornelius, Theodore, and Philip Galle, and Abraham and Cornelius Bloemart. The latter, perhaps less actuated by the commercial spirit in which the art was at this time practised, attempted improvements with success; and by working delicate tints on the lights, which had hitherto been left only as so many white spots, he brought his works to a degree of finish and harmony not previously attained. This artist studied and indeed died at Rome, whither also Goltzius travelled for improvement, who imparted a boldness to engraving which forms a striking contrast to the neat stiff manner of his predecessors. Goltzius was a man of great abilities, and drew the human figure admirably; but in endeavouring to avoid the dry Gothic taste of his countrymen, he went into the opposite extreme. The same observations will apply to the works of Sprangher; and these faults were exaggerated and carried to the extreme of bombast by the disciple of Goltzius, Müller; but the freedom with which he handled the graver is truly surprising. To these succeeded Lucas Killian, Matham, and Saenredam; and at the commencement of the 17th century the two Bolswerts, who had formed their style on that of Goltzius, improved themselves under the instructions of Rubens.

Etching, at this period, was practised by many of the painters in the Low Countries with great success; and we need scarcely say, that it is principally to this process that we are indebted for those treasures of art, the engraved works of Rembrandt: not that in his finished works he confined himself to etching; he also called in the assistance of the graver and the dry point. His etchings being very numerous, are of unequal merit; and many, the subjects of which are of a sacred or dignified nature, are debased by the vulgarity of the characters introduced: but notwithstanding these and other defects, his best works are greatly and deservedly prized, for they are inimitably fine, and possess the excellences of the best paintings, even by his own hand, in a degree not equalled by the works of any other engraver. To mention the artists of this school from whose hands we have etchings would be to name nearly all the most eminent painters belonging to it. Berghem, Cuyp, Karl du Jardin, Paul Potter, Ruysdael, Ostade, Waterloo, Adrian van de Veldt, with many others, have all enriched the portfolio of the collector with works of great taste and skill. Among the more professedly engravers not already noticed we must mention Count Goudt as possessing extraordinary skill, although he cultivated the art less as a profession than for pleasure. The family of the Visschers produced many and excellent works, from the pictures of various masters; and Cornelius Visscher stands particularly distinguished for the accuracy of his drawing and the fidelity with which he has rendered the character of the pictures after which he engraved.

In France engraving has been practised with pre-eminent success in the departments of history and portraiture. The celebrity of the school dates from the time of Louis XIV.; for although several engravers had appeared before that time, it was only under the fostering influence of that monarch, assisted by the fine taste of Colbert, his minister, that a school arose surpassing in excellence any which had preceded it. The family of the Audrans produced six eminent engravers, but of these the most distinguished was Gerard Audran. He was an admirable draftsman himself; but the great excellence of his works in other respects was enhanced by the absence of all *manner*, except such as belonged to the painter after whom he engraved. He was the first engraver who successfully united, to any extent, the use of the graver and the etching point, and by thus availing himself of the facilities arising from the use of the aquafortis, produced numerous works of great excellence and some of prodigious size, among which we may mention the battles of Alexander, after Le Brun, each subject of the series being engraved on three or four large plates. The Abbé Fontenac remarks of him that "far from conceiving that a servile arrangement of strokes, and the too frequently cold and affected clearness of the graver were the great essentials of historical engraving, he gave worth to his works by a bold mixture of free hatchings and dots, placed together apparently without order, but with an inimitable degree of taste, and has left to posterity most admirable examples of the style in which grand compositions ought to be treated."

Gerard Edelinck, although born at Antwerp, may be fairly considered of the French school, and was an engraver of the highest order. In portrait Nanteuil is no less celebrated than his contemporaries: the beauty and clearness of his style has perhaps never been exceeded. The Drevets (Peter Drevet in particular) are scarcely less distinguished; nor must we omit the name of John Louis Roullet, whose engraving of the 'Dead Christ with the fainting Virgin,' after Annibale Carracci, is one of the finest specimens which the art has produced. In addition we can only notice the names of Le Clerc, Simoneau, Chereau, Cochin, Dupuis, Beauvais, Baléchou, Le Bas, John George Wille, &c. &c. The modern and existing French school has produced very able engravers, whose chief defect is, that deviating from the course pursued by Gerard Audran and all the first artists, they allow that which is merely mechanical to predominate in their works; and aiming at great dexterity in the use of the *graver* as the chief objects, they make an ostentatious display of lines, the uniformity and regularity of which often imparts, even to the flesh, the appearance of net-work, when viewed closely.

The English school of engraving dates only from about the middle of the 17th century, but for another century the engravers who practised here were chiefly foreigners. The founder of the British school was William Faithorne the elder, one of the best portrait engravers of his age; he had able contemporaries and successors, but engraving was an exotic in England till the reign of George III., when with a school of painting arose an assemblage of engravers in all the departments of the art who may safely challenge comparison with those of any time or nation.

One of the earliest of these was Hogarth, an artist of most original genius, whose engravings were all from his own designs, in a walk of art entirely new. Landscapes had hitherto never been engraved in a satisfactory manner, the older engravers adhering to the use of the graver *only*, which was inadequate to express with sufficient freedom the playful luxuriance of foliage, the ruggedness of rocks, or the dash of foaming waters. These objects were first accomplished by Francis Vivares, who was a most accomplished etcher, and may be regarded as the father of English landscape engravers, who have unquestionably surpassed all their predecessors in this department of art. Woollett followed in the same tract, carrying his landscapes very forward with the etching point, and finishing them only with the graver. His best works are almost unrivalled; nor was he inferior in history, as his print of the death of General Wolfe, after West, sufficiently attests.

These two artists carried landscape engraving at once to perfection. Browne may be mentioned as a worthy follower; he produced many excellent plates after the old masters, and sometimes worked in conjunction with Woollett. In history and portrait Sir Robert Strange ably vindicated the honour of the art in this country: his engraving of flesh has perhaps scarcely been equalled, certainly never excelled by any master: his works are however often much deteriorated by his defective drawing. Mezzotinto engraving, although not strictly born among us, has been in no other country practised with a degree of success at all approaching that attained by M'Ardell, Earlom, Smith, Valentine, Green, and others. Bartolozzi, Ryland, Sharpe, Paul Sandby, Middiman, Milton, Fitler, are among the most eminent of deceased engravers; and Mr. Wilson Lowry is entitled to most honourable mention as a great benefactor to the art, by the invention of the ruling-machine, an instrument of great value for many purposes, and the operation of which is perfect. At present, every department of engraving is filled with artists of great abilities, any of whom it would be invidious to name to the exclusion of others: it is enough to say that their talents and their numbers have given the art a commercial importance in this country to which it never attained in any other.

A modern engraving is usually the result of two processes, namely, of direct incision with the graver, or the dry point, and of etching by corrosion. Line engraving is the highest branch of the art, and that which calls into exercise the full energies of the engraver. In it must be exhibited ample knowledge of the resources of the art, and a skilful handling of the burin. To produce really fine works, the engraver must be himself not merely a clever mechanicien, but an artist, possess the eye and mind of a painter as well as a thorough mastery of his tools. If he have the one as well as the other, he will know how to vary his lines almost indefinitely according to the character of his subject, and the nature of the objects he has to imitate.

The principal instrument of the engraver is the *graver* or *burin*, which differs in size and shape according to the character of the line which it is intended to produce; but the ordinary graver is of the form of a quandrangular prism, both square and lozenge-shaped, and fitted into a short handle, the whole being about five inches and a half long. The square graver is used in cutting broad lines, and the lozenge-shaped for more delicate ones. In making the incision, it is pushed forward in the direction of the line required, being held by the handle at an angle very slightly inclined to the plane of the copper. It is requisite that the graver be well tempered, and great address is necessary in whetting it for use. The angle at the meeting of the two lower sides of the graver forms what is called its belly, and the breadth of the end is called its face. The two sides which form the belly are to be laid flat upon the oil-stone, and rubbed firmly until the belly slightly rises, so that if it were laid flat upon the copper the light could be seen underneath the point; otherwise it would be impossible to use it with freedom, as it would dig unequally deep into the copper. The face is next to be whetted, which is done merely by laying the face of the graver flat upon the stone, with the belly upward, and rubbing it steadily upon a moderate slope until it acquires a very sharp point, taking care that the stone be properly supplied with oil all the while. The gravers sold in the shops are commonly too hard for use, which is known by the frequent breaking of their points: when this is the case they should be tempered by holding them on a red-hot poker, at a distance of half an inch from the point, until they acquire a faint straw colour; they should then be put into oil to cool; or they may be tempered in a candle and cooled in the tallow. But it is best not to be hasty in tempering; for if the graver is only a little too hard, whetting alone will frequently bring it into good condition. An instrument called a *scraper* is required to scrape off the barb or burr which is formed by the action of the graver and dry point. The *burnisher* is used to polish the plate and to erase any scratches which it may accidentally receive, and also to make lighter any part of the work which may have been made too dark. Much of the tone, air, and beauty of finish in a line engraving is due to the dextrous use of the burnisher. An *oil-stone* is requisite for sharpening the instruments upon. *Etching-points* or *needles* are nearly similar in appearance to sewing-needles, but fixed into handles four or five inches long; some are made of an oval form, to produce broader lines with: their use will be explained when we are describing the process of etching. *Dry point* is, in fact, nothing more than the common etching-needle brought to a very fine point. It is used to cut or scratch the more delicate lines with, such as skies, &c. &c. It does not, like the graver, cut the copper clean out, but throws it up on each side of the line produced by its progress through the metal: this is called the burr, which is removed by a scraper. This burr was left on by Rembrandt, until it wore away in the progress of printing, which it soon does; but by his management it added greatly to the effect of the etching, and impressions from his works with the burr on are much valued. A *cushion* is a bag of leather filled with sand; its use is to support the plate so that it may be freely turned in any required direction; but it is not now much used by artists, being chiefly confined to engravers of writing. A *rubber* is a roll of cloth tied up tight, one end being kept in olive oil. It is useful to polish off more completely the burr and also to show the appearance of the work as it proceeds.

Etching is one of the most important processes in modern engraving, almost all plates of every size and description being now commenced by this process, and indeed brought by it to a very considerable effect, and afterwards carried on to the necessary degree of finish and strength with the graver and dry point. Etching is the superaddition of the chemical process of corrosion to drawing, when performed on a plate of copper over which a substance called *etching-ground* is laid, and through which the design is traced with an etching-needle, so as to expose the surface of the copper wherever it has passed. This etching-ground is a substance composed of wax, asphaltum, gum mastic, resin, &c., incorporated by melting over a fire, and capable of resisting the action of aquafortis. The *laying of the ground*, as it is called, is thus effected:—The plate must be heated over a charcoal fire, so that it may not be smoked. For this purpose a hand-vice is fixed to the most convenient part of the plate, by which it may be held in the hand. A piece of the etching-ground, rolled into the form of a ball, and tied up in a little silk bag, is then rubbed over the surface of the plate, the heat of which causes the ground to melt and come through the silk on to the copper. In order to effect a more equal distribution of the wax, a small dabber made of cotton wool, tied up in a piece of taffety, is quickly dabbed all over the face of the plate while yet warm, so as to leave the wax or etching-ground of uniform thickness; the ground is then rendered black, by being held over the smoke of a wax candle, or, if necessary, two or three wax candles tied together, care being taken to move the plate about, so that it be equally smoked all over; and this operation of smoking must be commenced before the plate has had time to cool. The whole operation of laying the ground requires address and dexterity. When cold, the plate is now ready to receive the design. To transfer the design to the copper, an outline is made with a black-lead pencil on a piece of thinnish and even paper, and laid with the face downwards on the etching-ground; the whole is then passed through a rolling-press, the effect of which is to transfer an impression of the outline on to the smoked ground. After this the design is completed with the etching needles, which remove the ground from the copper wherever they pass, and expose it to the action of the acid during the process of biting in, which is thus performed:—A substance called *banking wax*, which when cold is quite hard, but which on immersion in warm water becomes soft, and may be moulded into any form, is first rendered soft by being so immersed in warm water, and then banked up all round the margin of the plate, so as to form a trough capable of preventing the escape of the acid, a gutter only being formed at one corner for the purpose of pouring it off when requisite. This being done, the nitric acid, reduced with water to the proper strength, is poured on, and its action on the copper becomes visible by the rising of innumerable bubbles. The nitric acid must be allowed to continue on the plate until the fainter parts are supposed to be corroded sufficiently deep; after which it is to be poured off, the plate washed with water, and left to dry. The parts which are bitten-in enough, are now to be covered with what is called *stopping-ground*, which is a mixture of lamp-black and Venice turpentine; this is applied with a camel-hair pencil, and allowed to dry. After this the acid is again poured on, and this process of *stopping-out* and *biting-in* is repeated until even the darkest parts are sufficiently corroded. After this the plate is again warmed, when the border of wax may be readily taken off. It is then made warm enough to melt the ground, which is removed by being wiped with a rag and a few drops of olive oil. The work is now complete, unless it is intended to finish it still further with the graver. We might offer rules for the strength of the acid, and state the length of time it ought to remain on the plate, but we are convinced of the inefficacy of such instructions. Nothing but experience, joined to some chemical knowledge of the effect of the acid, will avail the artist on this point, which requires the greatest nicety and attention.

Etching on soft ground is a mode of etching formerly much in use, by which imitations of drawings in chalk and pencil were produced. It is now, to a great extent superseded by lithography, which is more successful in attaining the same objects. Soft ground etching is quite a distinct process from

Engraving in stipple, as practised by Bartolozzi, Ryland, and others, in imitation of chalk drawings of the human figure. Stipple is performed with the graver, which is so managed as to produce the tints by small dots, rather than by lines, as in the ordinary method. It is very soft in its effect, but on the whole much inferior to the more legitimate mode of engraving.

Engraving on steel and *etching on steel* are performed in the same manner as on copper; steel having of late years been often substituted (for book-plates almost invariably) on account of its yielding a greater number of perfect impressions, owing to its superior hardness. The engraving is made on a plate of soft steel, which is subsequently hardened.

Aquatinta Engraving, and *Engraving in Mezzotinto*, are described under their respective titles. [AQUATINTA; MEZZOTINTO.]

Engraving on Stone, or more properly Drawing on Stone, is described, with the cognate process of *Engraving on Zinc*, under LITHOGRAPHY.

Etching on glass is performed by laying on the glass a ground of bees' wax, and drawing the design thereon with the needle, as in etching upon copper. Sulphuric acid is then poured on, and fluor spar, or fluoric acid, sprinkled on it. After four or five hours it is taken off, and the work cleaned with oil of turpentine.

Gem Engraving. [CAMEO; INTAGLIO.]

Medal Engraving. [COIN; MEDAL; DIE-SINKING.]

Machine Engraving. All the kinds of engraving hitherto noticed have been manual operations; the hand of the artist has guided his tools, and the result has depended on the manipulative dexterity no less than on the artistic taste of the engraver. Within the last few years, however, several methods have been introduced of engraving by the assistance of machinery, thus superseding the manual operations of the engraver. The earliest and simplest machine for engraving, the Ruling-Machine, of Mr. Lowry, has already been mentioned. Its object, however, was to assist, not to supersede, the engraver's handiwork; its application being confined to skies, plain back-grounds, and other portions where, if executed by the engraver, the operation was purely mechanical. The saving of labour effected by the ruling-machine is very great, and it has consequently come into very general use. But what is known as *Machine Engraving* is executed wholly by machinery. The machine, however, wonderful as are its operations, is not capable of artistic work. It can execute designs for a great many business purposes, but its chief application hitherto has been to the engraving of bank-notes. [BANK-NOTE MANUFACTURE.] Several machines have been invented for this purpose, but it would be of little use to describe their complex mechanism, if even it were open to description; but it is, in fact, as much as possible kept secret. The principle of all these engraving machines is that of the pantograph [PANTOGRAPH], but the application is complicated by being united with that of the Rose or Guilloche Machine, a familiar employment of which is seen in the beautifully carved ("engine-turned") lines engraved on watch-cases. Messrs. Perkins and Heath were, we believe, the first to introduce this machine practically, and many of their bank-notes and cheques were admirable specimens of workmanship.

The latest and most perfect machine for engraving is that of Mr. F. G. Wagner, of Berlin, which he calls the "Universal Rose-Engine or Guilloche Machine." This machine has besides the Guilloche apparatus, a centric apparatus connected with two excentric, an oval, an angle, and two radiating apparatuses; an apparatus connecting the guilloche and centric apparatus, an apparatus to produce spiral-wave lines in every different shape, and a volute-line apparatus; and these all admit of being used separately, or in combination, in so many ways, and their separate or combined employment can be so variously modified by the distinct motions of the carriages, &c., that a practically unlimited number of patterns can be produced, comprising an endless variety of curved, waving, and spiral lines, drawn with mathematical precision. "The machine," observes Mr. Henry Bradbury, (who has the exclusive possession of it in England,) "is set in motion by means of levers, tooth-wheels, and handles, by which the motive power has no influence whatever upon the correctness and delicacy of the patterns,—properties infallibly guaranteed by the arrangement of the machine. Owing to this simple manipulation, the entire attention may be concentrated upon the composition of patterns, offering a boundless field to the inventive spirit. In spite of the many apparatuses and actions which combine to constitute the Guilloche machine, the management of it is very simple. All the portions remain in constant connection with one another, and may, by means of arrangements of a very simple character, be immediately set in motion, or stopped, as circumstances may require." The machine itself is a singularly elegant piece of mechanism, and unlike the earlier engraving machines, it occupies a comparatively small space.

Medallic Engraving.—In 1830, M. Achille Collas invented a machine for engraving representations of medals, coins, and other objects in relief, which representations should afford to the eye a similar appearance of relief to the medal itself. Shortly afterwards, Mr. Sexton, in America, and Mr. Bate, in London, invented machines which effected a similar object, and, as was said, without a certain "distortion" inevitable in the old machine. A warm discussion was for some time carried on between the advocates of the French and English machines, and their respective merits even engaged the attention of a committee of the House of Commons.

The principle of all these machines is the same. The process of copying medals by them may be familiarly illustrated by a reference to that of the *Silhouette* or profile machine: that is, a pointer at one end of a lever traces over the object to be copied, and a pointer at the other end executes the copy itself. We may suppose a medal to be laid down flat, and that placed near it is the copper-plate on which the engraving is to be made. A peculiar bent lever touches them both, having a tracer-point at one end and an etching-point at the other; the tracer-point comes down vertically on the medal, whereas the etching-point comes nearly horizontally into contact with the etching-ground of the copper-plate. When the tracer-point passes over a flat or level part of the medal, the etching-point marks or engraves a horizontal line on the etching-ground; but when the tracer rises over any of the relief parts of the medal, the etching-point makes a curved line, more or less convex in proportion to the boldness of relief. By passing the tracer-point over every part of the surface of the medal, in parallel lines, the etching-point is made to mark an equal number of lines on the etching-ground of the copper-plate; but these latter lines, instead of being straight and parallel, have varying degrees of curvature. In passing over a sloping part of the device on the medal, the lines in the engraving become either more closely placed or more widely separated than in the former case, according to the direction taken by the sloped surface; they thus give the light-and-shade appearance of a surface in relief. In the original machines, M. Collas carried the tracing-point over the medal vertically, Mr. Bate at an angle of 45°, by which much greater accuracy was ensured. Both these gentlemen subsequently made several improvements in their machines; and other machines, differing in the details, have been invented. The latest, the most elegant as a piece of mechanism, and the most compact, is that of Mr. Wagner, the inventor of the Guilloche engraving machine, noticed above. Among its advantages are, the facilities with which by means of it "copies of relief, in the same proportions as the model, in augmented or diminished proportions, reversed or otherwise, of more or less plastic expression than the model, and of a different point of view, can be produced."

Electro-Magnetic Engraving.—Among the multiplicity of projects which have been put forth for the employment of electro-magnetism, have been several for producing engravings. The earliest machine of this kind that we know of was one by Mr. Hansen, a German, in 1854; one of the latest, that of an American, Mr. Brooman, in 1858. In these machines, as in the engraving and medal machines above described, the incision in the copper-plate is made by a graver working at one end of a bent lever, or series of levers, corresponding in its motion with a tracing-point at the other end, which is carried over the design to be copied. But in these machines the action of the graver is produced by the alternate making and breaking of contact, as is described under ELECTRO-MOTIVE MACHINES. In Mr. Hansen's process, the design is drawn on a metal plate, with a resined ink or other non-conducting substance. In Mr. Brooman's, the pattern-plate is coated with varnish or other non-conducting material, and the design is drawn on it down to the metal. The tracing-point is made to travel successively over every part of the pattern-plate, and whenever it comes in contact with a conducting surface the graver will be pressed down upon the plate to be engraved, and the engraving process will go on till the tracing-point meets with the non-conducting surface, when the circuit will be broken and the graver lifted off the plate. This is continued till the whole of the design is passed over, when a fac-simile of it will have been engraved. We are not aware that any of these electromagnetic machines have been brought into practical operation: the idea is ingenious, but its successful application is very doubtful.

Photographic Engraving. How to employ the Sun as an engraver, is a problem which has engaged the attention of many photographers and men of science in America as well as in Europe. The more successful of their processes will be noticed under PHOTOGRAPHIC ENGRAVING.

Reproduction of Plates.—One of the earliest plans for reproducing engraved plates was that of Messrs. Perkins & Heath. A cylinder of soft steel was passed over an engraved steel-plate, which had been properly hardened, until it received the impression in relief. The cylinder was then hardened, and being rolled upon a *soft* steel plate, transferred to that a fac-simile of the original engraving capable when hardened of yielding impressions as sharp as the original plate. Of course, the cylinder being very hard, several plates could be thus taken from it. The process has been largely employed for commercial purposes, but not as far as we know for artistic work. For both purposes, but especially for the latter a process equally efficacious and less likely to injure the original plate, was discovered in the Electrotype, by which any number of repetitions of a copper or even steel plate, of whatever size or delicacy of execution, may be produced with absolute safety and at comparatively small cost. The process is described under ELECTRO-METALLURGY. It has been extensively employed in the manufacture of bank-notes.

The singularly ingenious *Electro-Block* process of Mr. Collins, by which engraved fac-similes of engravings or designs, of either the same, a larger, or a smaller size, or of altered form, can be produced without the aid of a draughtsman or engraver, is noticed under EARTHENWARE. It is chiefly applied at present to the reproduction of blocks for surface-printing, but it is also applicable to the reproduction of incised plates.

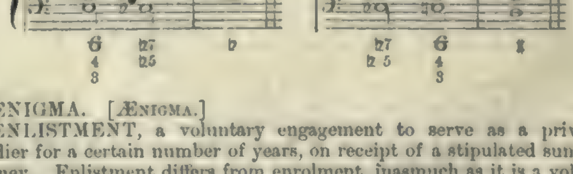
One of the most recent applications of science to the art of engraving, consists in coating the engraved plate with a thin film of some other metal by means of the galvanic battery. Attention was first called to this invention by M. Joubert who in 1858 took out a patent for covering copper plates with an extremely thin coating of iron, a process which he designated *acieraging*. Plates so coated will yield, he found, from 5000 to 9000 impressions; and whenever it may appear desirable, the printing can be stopped and a new coating be applied. Mr. Henry Bradbury shortly afterwards published in the 'Journal of the Society of Arts' (vol. vii. p. 172, &c.), a method he had employed with success, for coating engraved plates with a deposit of zinc, by means of chloride and cyanide of zinc, and a Smee's battery. A plate so coated he found will yield from 1500 to 2000 impressions; and when it shows signs of wearing, the coating can be removed and renewed at pleasure, with great facility and without injury to the plate. He has since employed nickel, which yields 5000 impressions, in the place of zinc, with equal facility, and with little additional cost.

ENGRAVINGS. [COPYRIGHT.]

ENGROSSING; copying in a large hand; the writing a deed in fair, legible characters; from the French *grossir*, to make bigger. Among lawyers it more particularly means the copying of any writing fair upon parchment or stamped paper.

Engrossing also means the purchasing of large quantities of any commodity, in order to sell it again at a high price. It was formerly a very serious offence, but the statutes making Forestalling, Regrating, and Ingrossing criminal, after being long in desuetude, have been entirely repealed. (Blackst. 'Com.' Mr. Kerr's ed., vol. iv.)

ENHARMONIC, the third in order of the three genera of ancient music. The enharmonic genus of the Greeks was distinguished by quarter tones, while the modern scale admits these small intervals theoretically only, not practically, except by a fiction. Thus C sharp and D flat are with the moderns practically the same note, at least on keyed instruments, though, strictly, the former is $\frac{15}{16}$ of the whole string sounding C, the latter $\frac{9}{10}$. The passage from one to the other of these intervals is called an *enharmonic change*, and a change of key so effected is designated by the term *enharmonic modulation*. Examples:—



ENIGMA. [ÆNIGMA.]

ENLISTMENT, a voluntary engagement to serve as a private soldier for a certain number of years, on receipt of a stipulated sum of money. Enlistment differs from enrolment, inasmuch as it is a voluntary act, whereas the latter is, under some circumstances, rendered compulsory: as in the case of men who are selected by ballot for the militia in this country, or who have served in her Majesty's forces, and are enrolled in the Reserve Force under the 22 & 23 Vict. c. 42, or who are raised by conscription for military service generally on the continent.

The practice of impressing men to serve as soldiers, on sudden emergencies, was formerly very common in England; and it is well known that young men were entrapped and secretly conveyed away to recruit the armies employed in the east. The discovery of this illegal and disgraceful method of obtaining soldiers was speedily followed by its abolition; and now, the Indian army, like her Majesty's other forces, is recruited by voluntary engagement.

The number of young men who are induced to enlist by the ambition of entering upon a course of life which appears to hold out a prospect of distinguishing themselves by gallant achievements in the field is, however, too small for the wants of the military service; and the allurement of a bounty must necessarily be presented in order that the ranks of the army may be filled. But the profession of a soldier can never possess such advantages as might induce an industrious man who can obtain a subsistence in another way to embrace it; and it is to be regretted that too frequently those who enter the service are thoughtless youths or men of indolent habits or desperate fortunes. Some attention, however, to the character of a person offering himself for enlistment is necessary if it be desired to render the service honourable: for it is found that idle and dissipated men are with difficulty brought to submit to the necessary restraints of discipline; their frequent desertions entail heavy losses on the government, and they often corrupt those who are compelled to associate with them. When circumstances render it necessary to enlist such men, it is obvious that they ought to be distributed in small numbers among different regiments, and quartered in places remote from those from which they were taken.

By the Mutiny Act it is declared that every person who has received enlisting-money, knowing it to be such, from any military man employed in the recruiting service is to be deemed to be enlisted as a soldier; but within forty-eight hours, and not sooner than twenty-four hours afterwards (any intervening Sunday, Christmas-day, or Good Friday not included), notice is to be given to the recruit, or left at his place of abode, of his having so enlisted; and again, ninety-six hours (any intervening Sunday, Christmas-day, or Good Friday not included), but not sooner than twenty-four hours, from the time of receiving the money, the recruit, attended by any person employed as aforesaid, is to appear before a magistrate (not being a military man), when, if he declare that he has voluntarily enlisted, the magistrate is to question him concerning his name, age, and condition, and physical capacity to serve, and particularly to inquire of him whether he is then serving, or whether he have ever served, in the army or navy. The magistrate is then to read to the recruit the articles of war relating to mutiny and desertion, and administer to him an oath of allegiance, of which a form is given in a schedule to the Act; if the recruit refuse to take the oath, he may be imprisoned till he do so.

But as the young and simple have been sometimes inveigled by illusory promises, or persuaded, while deprived of judgment by intoxication, to enlist, if a recruit, on reflection, wish to withdraw from the engagement into which he may have been surprised, it is provided by the Mutiny Act that when taken before the magistrate as above he shall be at liberty to declare his dissent from such enlistment; and on making this declaration and returning the enlisting-money, with 20*s.* as smart-money, and all pay received by him as a recruit, he shall be forthwith discharged. But if he omit within twenty-four hours after declaring his dissent to pay such money, he is to be considered as enlisted, as if he had given his assent before the magistrate.

If a recruit, after receiving the enlistment-money, and, after notice of having enlisted has been left at his place of abode, shall abscond, he may be apprehended and punished as a deserter, or for being absent without leave; and if it be discovered that he is unfit for active service, in consequence of any infirmity which he had not declared before the magistrate, he may be transferred to any garrison, or veteran or invalid battalion, though he may have enlisted for some particular regiment. If it be proved that the recruit concealed the fact of his being a discharged soldier, or any infirmity which incapacitates him for the service, or made any false representation, he may be sentenced to suffer punishment as a rogue and vagabond; and if in consequence of false representations he shall have obtained enlisting money, or bounty, he may be prosecuted for obtaining money under false pretences, or in Scotland for falsehood, fraud, and wilful imposition; and if, at the time of enlisting, he falsely denied being in the militia, if a volunteer, he may be committed to the House of Correction for any time not exceeding fourteen days, and if a substitute or balloted man, for any period not exceeding six months; and, from the day in which his engagement to serve in the militia ends, he is to be deemed a soldier in the regular forces.

An apprentice who shall enlist, denying himself to be such, is deemed guilty of obtaining money under false pretences; and, after the expiration of his apprenticeship, he is liable to serve in her Majesty's forces; but a master is not entitled to claim an apprentice who may have enlisted unless the claim be made within one month after the apprentice shall have left his service, and unless the apprentice shall have been bound in England (when not above fourteen years of age) for seven years, or in Ireland and the British Isles (when not above sixteen) for five years, or in Scotland by regular contract or indenture for four years.

In the Mutiny Act it is also enacted that no man enlisted as a soldier is liable to be arrested on account of any process for leaving any relation or child chargeable to a parish, or on account of any engagement to work for an employer (except that of an apprenticeship), or on account of any debt under 30*l.* It is enacted that all negroes or persons of colour, although not born within the possessions of the crown, who shall voluntarily enlist, and all negroes purchased for the crown previous to the abolition of slavery, and all negroes seized and condemned as prize under the slave trade Acts and appointed to serve in the army, shall while serving be deemed to be soldiers legally enlisted, and be entitled to all the privileges of natural born subjects. Every military officer acting contrary to the provisions of the Mutiny Act, in what regards enlisting recruits, is liable to be cashiered.

During the reign of Queen Anne it was the custom to enlist recruits for three years; but this period seems too short, considering the time unavoidably spent in training the men, to afford the government an advantage adequate to the expense of maintaining them; and the practice which afterwards obtained of enlisting for an unlimited period was deemed by parliament to be impolitic. It was therefore enacted by the 10 & 11 Vict. c. 37, that no person should be enlisted for the British army or the Indian army to serve in the infantry for a longer period than ten years; or in the cavalry, artillery, or ordnance corps, for more than twelve years; reckoning from the day of attestation, or on which the recruit shall attain the age of eighteen, whichever is latest, subject however to any order in council shortening such period by virtue of a temporary Act subsequently passed.

The advantages of a limited period of service are, that a greater number of recruits are obtained under that condition, probably because men are more willing to engage themselves for a certain number of years than for life; and that, during the period, opportunities are afforded of discovering the character of a man. Should this be such as to render it not advisable to retain him, he may be discharged at the end of his time of service; while an additional bounty, strengthened by the unwillingness of most men to leave the comrades with whom they have been long accustomed to associate, will probably induce a good soldier to re-enlist should the continuance of his services be desired.

By the 5 & 6 Will. IV. c. 24, and the 16 & 17 Vict. c. 69, together with certain orders in council approving and confirming the recommendations of the Board of Admiralty, a man may enter himself on the books of the Royal Navy for a period of five years, or with increased pay and other advantages for continuous and general service during ten years, after which he is entitled to his discharge, and to be sent home if abroad, unless the commanding officer should consider his discharge detrimental to the service. Such officer is in that case empowered to detain the man six months longer, or until the emergency shall cease, and the man so detained is entitled to twopence a day in addition to the pay of his rating. The crown is empowered to require by proclamation any one in the navy to continue to serve for any time not exceeding five years after the expiration of his period of service; but the man so detained is entitled to any bounty offered by the proclamation.

The period of enlistment in the Marines is determined by the 10 & 11 Vict. c. 63 to be twelve years, subject to any reduction of that period to be made by order of the Board of Admiralty, in pursuance of the 20 Vict. c. 1. The Board of Admiralty are also empowered by the 16 & 17 Vict. c. 73 to raise a body not exceeding 10,000 men to be called the "Naval Coast Volunteers," to be enlisted for five years, to be out for training either on shore or shipboard twenty-eight days in each year, and to be liable in case of imminent national danger to be called into active service by royal proclamation; and by the 22 & 23 Vict. c. 40, to raise a reserve force of 30,000 men, to be called the Royal Naval Volunteers, subject to similar conditions and liable to similar services. The coast-guard as previously constituted, and capable of being increased to 10,000 men, has also been placed under the control of the Admiralty, and made subject to similar discipline to that which prevails on board the Royal Navy.

By the 59 Geo. III. c. 69 it is made a misdemeanor, and punishable accordingly, for any British subject to enlist, or consent to be enlisted, to serve in any foreign army or navy.

ENOCH, the Book of, is one of the Hebrew Scriptures which, with several others, were designated Apocryphal. [APOCRYPHA.] During the apostolic age the book of Enoch was commonly read by Jews and Christians. St. Jude, in his catholic epistle, cites it as the work of a divine prophet ("Enoch the seventh from Adam prophesied, saying," &c., v. 14, 15), so Tertullian ('De Idolatria') refers it to the inspiration of the Holy Spirit: however, in another treatise ('De Cultu Fœminarum') he states that by some it was not received. Irenæus, Jerome, and other fathers, respectfully notice it, though not as canonical; and Origen ('contra Celsum,' lib. v.) observes that, in his time, it was not of great authority in the churches. In the Testament of the Twelve Patriarchs, translated by Robert Grosthead, bishop of Lincoln, the sons of Jacob speak often of reading in the book of Enoch. It was extant among Christian writers until the 8th century, when it appears to have been lost. Several fragments, however, remained, which, with a few citations collected from the fathers and succeeding writers, supplied the only data for the critical discussions of learned divines during several centuries. All these relics, amounting to about 20, are inserted in the 'Codex Pseudepigraphus Vet. Test.' of Fabricius, tom. i. p. 160–224.

At the end of the 18th century Bruce brought from Abyssinia three complete and beautiful copies of the book of Enoch, in the Ethiopic language, one of which he presented to the Bibliothèque du Roi at Paris, and another to the Bodleian Library at Oxford. Transcriptions and partial translations into Latin were made by Dr. Woide of Oxford and Dr. Gesenius of Halle; but the Ethiopic MS., which at first excited much curiosity, lay undisturbed during more than a quarter of a century, until the professor of Hebrew at Oxford, Dr. Lawrence, broke in, as he informs us, upon its repose, and published in 1826 an English version of the whole, entitled 'The Book of Enoch the Prophet, supposed for ages to be lost; translated from an Ethiopic MS. by the Rev. Richard Lawrence, LL.D., archbishop of Cashel.' A second and revised edition appeared in 1833. That this book is identical with that which, in the primitive ages of Christianity, was cited by Jude and the fathers, is considered by Dr. Lawrence to be completely evident. His critical prolegomena and notes are incorporated in a more recent translation into German, which is accompanied with a much larger mass of learned researches, forming two thick volumes 8vo. ('Das Buch Henoch, in vollständiger übersetzung mit fortläufenden Commentar, ausführlicher einleitung, und erläuternden excursen, von Andreas Gottlieb Hoffmann, Doct. Philos. Profess. Theol. an der Univers. zu Jena,' 1833.) As the allegorical statements of the book, as far as any meaning is clearly assignable, appear to relate to historical events which extend to the time of Herod the Great, it is supposed by those who reject the supposition of its being the antediluvian production of Enoch himself that it was anonymously written in Hebrew, shortly before the commencement of the Christian era. (Scaliger and Lawrence.) The subject matter consists chiefly of relations of Enoch's prophetical and celestial visions, in the most remarkable of which the angel Uriel (lxx. et seq.) shows to the prophet all the mysterious scenes in heaven, including a survey and explanation of the solar and lunar revolutions according to the ancient astrological theory. A view is also exhibited of the interior of hell. Occasionally religious and moral precepts are enjoined, but all sense of propriety is continually shocked with such preposterous combinations that Scaliger, judging merely from the fragments then possessed, scrupled not to designate the book as a tissue of disgusting lies and nonsense. ('Scaligeriana.') It commences with some historical statements, of which the following, from chap. 7, is a specimen:—"To the sons of men were born elegant and beautiful daughters, and when the angels, the sons of heaven, beheld them, they became enamoured of them, saying to each other, 'Come, let us select wives for ourselves and beget children.'" Accordingly a band of 200 angels having descended on Mount Arnon, and sworn to accomplish this project, "they then took wives, each choosing for himself; with whom they cohabited, teaching them sorcery and incantations; and the women conceiving, brought forth giants, whose stature was each three hundred cubits (450 feet): these, when they had devoured all the produce of man's labour, began to devour men, birds, beasts, and fishes, eating their flesh and drinking their blood." In representing persons and events by animals and inanimate objects of nature, combinations are introduced of such a monstrous nature, that, in comparison, the metamorphoses of the Pagan mythologies appear to be rational. The history of the prophet to whom this book is attributed, or rather whose visions it relates, is briefly recounted as follows, in Genesis v. 18–24:—Jared at the age of 162 begat Enoch, who at the age of 65 begat Methuselah, and afterwards walked with God 300 years, and begat sons and daughters. All the days of Enoch were 365 years; he walked with God, and was not, for God took him. (Compare Ecclesiasticus xliv. 16; Heb. xii. 5.) From the fact of his being the seventh from Adam, from the number of the years of his age being precisely the number of days in the year, and from several other points of curious coincidence, the sceptical Boulanger asserts, in a learned treatise on the subject ('Enoch,' in 'Œuvres Diverses'), that the name is but a variation of the Phrygian Annac, a symbolical personification in Sabism, representing the solar period; and identical with the Oriental Anusch, the Phœnician Anac or Enac, the Etruscan Anus, and the Latin Janus.

ENROLMENT, in law, is the registering, recording, or entering a deed, judgment, recognizance, acknowledgment, &c., in Chancery or in some other court having authority to receive such enrolments. The enrolling does not make a deed a record, though it thereby becomes a deed recorded; for there is a difference between a matter of record and a thing recorded to be kept in memory; a record being the entry of judicial proceedings in a court of record; whereas an enrolment of a deed is the private act of the parties concerned, of which the court takes no judicial notice. Various statutes have directed instruments to be enrolled, the best known of which is the 27th Henry VIII. c. 16, relating to deeds of bargain and sale of freehold lands. The registration of bills of sale [BILL OF SALE] is of the nature of an enrolment, although every registration of a deed is not. Thus deeds relating to property in the counties of York and Middlesex are registered in the registrar-offices there established by statute: they are not enrolled.

ENSIGN, a commissioned officer, the lowest in degree, and immediately subordinate to the lieutenants in a regiment of infantry. One of this rank is appointed to each company, and the junior ensigns are charged with the duty of carrying the colours of the regiment. Ensigns in the regiments of foot guards have also the rank of lieutenants. In the Rifle Brigade, Fusileer regiments, and in the royal corps of Artillery, Engineers, and Marines, in place of an ensign a second lieutenant was formerly attached to each company. The title of second lieutenant is now however abolished, the title of ensign being resumed in the Rifle Brigade and Fusileer regiments; whilst in the Artillery, Engineers, and Marines, all the subalterns are called lieutenants, those that would have been second lieutenants, however, only receive second lieutenant's pay.

Among the Spaniards and Italians, in the 17th century, it appears that no officer existed like the lieutenant of a company, whose rank is between that of a captain and ensign, any such being considered superfluous, and as tending to diminish the importance which was attached to the post of the officer who had the charge of the colours, on the preservation of which in action, the honour of the regiment was made greatly to depend.

When, as formerly, a battle partook far more than at present of the nature of a melée, the loss of a standard, which served as a mark for the soldiers under each leader to keep together in the fight or to rally when dispersed, must have been a serious misfortune, and probably was often attended by the total defeat and destruction of the party; and hence, no doubt, arose the point of honour respecting the colours. A French military author, who served and wrote in the time of Charles IX., intending to express the importance of preserving the colours to the last, observes that, on a defeat taking place, the flag should serve the ensign as a shroud; and instances have occurred of a standard-bearer who, being mortally wounded, tore the flag from its staff and died with it wrapped about his body. Such a circumstance is related of Don Sebastian, king of Portugal, at the battle of Alcazar, and of a young officer named Chatelier at the taking of Taillebourg, during the wars of the Huguenots.

In the old French service, the duty of carrying the oriflamme at the head of the army was confided to a man of rank, and also of approved valour and prudence. The post was held for life.

The price of an ensign's commission in the foot guards is 1200*l*., and his daily pay is 5*s*. 6*d*.; in the regiments of the line the price is 450*l*., and the daily pay 5*s*. 3*d*.

ENTABLATURE. [COLUMN; GREEK ARCHITECTURE.]

ENTAIL. [ESTATE.]

ENTERI'TIS, *Inflammation of the Intestines.* The inflammatory affections of the whole alimentary canal constitute an extensive and highly important class of diseases, several of which are properly designated by specific names, since they have a peculiar seat and require a peculiar treatment. Enteritis is one of these. This term is employed to denote an acute inflammation of the external or peritoneal coat of the intestines. When inflammation is seated exclusively or chiefly in the peritoneal coat of the intestines, both the local and the constitutional affection is widely different from that which is produced when inflammation is seated in the mucous coat. It is, therefore, with good reason that these diseases are distinguished by different names.

The distinctive characters of enteritis are pain in the bowels, vomiting, invincible constipation, fever, and sudden and great prostration of strength.

The pain is often exceedingly severe, and is usually especially acute about the navel. The inflammation may be confined to a small portion of the intestines, or its seat may be very extensive. The pain is felt in the part in which the inflammation is seated: hence the pain is occasionally restricted to a particular part of the abdomen; but far more commonly it is spread over a large portion of it, and, as has just been stated, is peculiarly severe about the navel. The pain is constantly present; it is never for a moment entirely absent; but it is occasionally very much aggravated in paroxysms. It is always greatly increased by pressure over the seat of the part inflamed. Though severe pain be a very constant attendant on enteritis, yet occasionally cases occur in which the pain is never so great as to occasion much alarm, and these insidious attacks are the most dangerous.

The vomiting, though occasionally absent, is pretty constantly present, and is sometimes frequent and most distressing. In the intervals between the acts of vomiting there is a sense of nausea. It has been thought that when the vomiting is urgent, it is an indication that the inflammation has extended to the stomach; but the inspection of the body after death has fully shown that there may be most distressing vomiting when not the least appearance of disease can be traced in the stomach.

Obstinate constipation is a diagnostic mark of enteritis. It is not, indeed, invariably present; but it is present in so large a proportion of cases, that when absent it must be considered as an exception to the general rule. Its absence should leave no doubt upon the mind of the nature of the attack if the other symptoms are present.

More or less fever is always present. The skin is usually hot and dry, and the heat is often preceded by a sense of chilliness or by a distinct rigor. The tongue is usually white and furred; there is much thirst, and the pulse is quick, small, sharp, and incompressible.

The expression of the countenance is peculiar. The features are sharp and compressed; in severe cases, and in almost all cases in the advanced stage, quite sunk. The expression is anxious and wild, and the first glance conveys to the beholder an irresistible conviction that the individual is labouring under some intense internal disease.

The impression upon the powers of life is so great and rapid that he patient is far more exhausted after a few hours' illness in this disease than after an attack of as many days' duration in most other acute maladies. This rapid and extreme prostration is highly characteristic of enteritis; and if it be combined with any one of the symptoms which have been described, should leave no doubt of the existence, in an intense form, of one of the most dangerous diseases to which the human body is subject.

As the inflammation advances, the pulse becomes more rapid and feeble; the abdomen swollen, tense, and tympanitic; the prostration increases; the skin, instead of being hot, becomes cold and clammy, and the extremities, more especially, are cold.

The inflammation has a peculiar tendency to terminate in gangrene. Before this event happens, it is usually conceived that the inflammatory action extends from the peritoneal to the muscular coat, and that in the most intense cases all the coats of the intestine become involved. The signs that mortification has taken place are, cessation of pain, hiccup, increased frequency and weakness of the pulse, greater collapse of the countenance, and increased prostration. But it is remarkable, that often when the patient dies under the ordinary symptoms of mortification, on the examination of the intestine after death, nothing can be detected but the usual appearances of inflammation; there is no trace of a gangrenous spot; death is produced by the intensity of the inflammation.

The brain usually remains unaffected to the end; the mental faculties are but little impaired; but sometimes, as the disease advances, the mind becomes confused and wandering, and occasionally delirium sets in early,—a certain sign that the disease is of extraordinary intensity.

The exciting causes of the disease are, acrid and indigestible matters taken into the stomach in large quantity; habitual full living on highly seasoned food; the accumulation of hardened fæces; cold drinks, especially when the body had been previously overheated. But perhaps the most common cause of the disease is cold, combined with moisture, applied either directly to the abdomen, or to the body generally, and more especially to the lower extremities. It is also frequently superinduced by strangulated hernia; and on the sudden occurrence of the symptoms of enteritis the abdomen should always be carefully examined, with a view to ascertain whether hernia be present. It may also be caused by an event which cannot be known until after death,—the involution of one fold of the intestine within another (intus-susception or volvulus), so as to occasion a complete obstruction to the passage of the contents of the bowels.

Enteritis can scarcely be confounded with any other disease excepting colic, and the relation between these two affections is so close that severe colic is very apt to lapse into enteritis; and this it is very important that the practitioner should bear in mind. But when colic exists as a distinct disease it is clearly distinguished from enteritis by the absence of fever, and of the prostration so characteristic of enteritis; by the occurrence of the pain more decidedly in paroxysms with intervals of complete ease; by the diminution, not the increase, of the pain on pressure, and by the strikingly different state of the pulse.

Enteritis may attack persons of all ages, from the infant a day old to the man who reaches the extreme term of human life. It may occur at all seasons of the year. Its attack is often sudden, and it sometimes proves fatal with frightful rapidity. It is by no means uncommon for a person apparently in sound health to be destroyed by this disease within twenty-four hours from the commencement of the attack.

Hence the importance of a knowledge of its early symptoms, and the necessity of attacking it with the utmost promptitude and vigour. The ordinary remedies for inflammation must be employed with decision. The character of the pulse, the sunk countenance, the prostration of strength, may appear to contra-indicate blood-letting; but these are false indications, and if regarded, the event will be fatal. After a copious bleeding the pulse often diminishes in frequency and increases in strength; the expression of the countenance improves, and the vital energies recover, as if the system were relieved of an oppressive load. Bleeding must be carried as far as possible, until it appears to have made an impression upon the inflammatory action. It is a very useful practice to bleed from the arm two or three times in succession, after an interval of two or three hours, if the symptoms of inflammation do not abate.

It is without doubt highly desirable to procure evacuations from the bowels; but the disease is to be cured by the removal of the inflammation, not by opening the bowels. Death often takes place though the bowels are opened, and the fatal event is not unfrequently hastened, if not brought about by the acrid nature of the cathartics given to remove the constipation. These acrid cathartics, if they open the bowels, do not necessarily save the patient; and if they do not open the bowels they greatly increase the inflammation. Only the mildest aperients should be employed. This is one of the diseases in which the judicious employment of calomel and opium is attended with the best results.

Colic is often converted into enteritis, or a case of enteritis mistaken for colic is frightfully aggravated, by taking spirituous cathartics, as tincture of rhubarb, for the relief of the pain. In no case whatever should any vinous or spirituous cathartic be taken for pain in the bowels, however slight, without the sanction of a medical man. Persons continually sacrifice their lives by taking brandy, or a large dose of some tincture, for what they call spasm of the stomach or bowels. The so-called spasm oftentimes is inflammation, which the stimulus of the alcohol increases to such a degree that the disease is no longer to be restrained by any remedies that can be employed.

Inflammation of the mucous membranes of the intestines, called *enteria*, or *enteritis erythemoidea* is attended with a different set of symptoms. In this case, the bowels are generally relaxed. There is griping pain which is generally referred to the umbilicus or right iliac porea. There is inclination to sickness, and the bowels are frequently distended with flatus. There is coldness of the surface, with frequent shivering. The tongue is moist, but viscid, clammy, and furred. The abdomen is not tender when pressed, but there is a general sense of uneasiness. The stools are at first feculent and large, but afterwards become scanty, frequent, and watery, containing undigested food, and sometimes blood.

In these cases the mucous membrane is highly congested, and ulceration is constantly present.

The treatment consists of bleeding by leeches, warm fomentations, acting on the bowels by gentle purgatives combined with opiates. Where the pain is violent opium should be given to relieve the pain.

ENTOMO'LOGY, that branch of science which treats upon insects. The term *entomology* literally signifies a discourse upon insects, it being derived from the two Greek words, *éntomon*, an insect, and *logos*, a discourse.

The term entoma was first applied to these animals by Aristotle, and is synonymous with the Latin word insecta (whence is derived the English name *insects*), both having reference to a striking character exhibited in the insect tribe, that of having the body *insected*, or, as it were, cut and divided into numerous segments.

ENTOZOA. [WORMS.]

ENTRESOL, a French term used to signify a floor between other floors. The entresol consists of a low apartment or apartments, usually placed above the first floor. The Italian form, mezzanine, is now perhaps more frequently employed than the French one; and the mezzanine is in London often placed above the ground floor. In street architecture it is desirable to form the basement story on a scale of grandeur, and in so doing a greater space than necessary would frequently be given to the first floor, if it were not for the entresol.

There is a good example of an entresol in the Regent Street Quadrant in London, and it has been introduced in many other cases where the lower floor has been intended for shops. The entresol is a frequent feature in the architecture of Paris.

ENTRY (from the French *entrée*, and Latin *intrare*, to enter), in Law, is a taking possession by the legal owner of lands and tenements when another person is wrongfully in possession of them. At the common law this might be effected by force; but as it was the cause of great abuses, forcible entries were made punishable by fine and imprisonment by two statutes of Richard II., which were enlarged by the statute 8 Henry VI. c. 9.

The effect of an entry was formerly to keep alive the assumed right of the person making the entry to the premises he entered on. This was effected by an annual repetition of the entry, which was called *continual claim*. The party availing himself of this summary process entered upon some part of the property claimed, and formally declared that thereby he took possession of the whole; and the entry was repeated in each county in which the lands lay.

The statute 3 & 4 Will. IV. c. 27, in effect abolished this practice by making twenty years' possession a good title to land, and at the same time abolishing the ancient writs of entry, which the *continual claim* above alluded to entitled the party to bring at any time. An entry on lands has accordingly no effect now, unless the tenant in possession admits the right of the person making the entry, the effect of which is that he is at once in possession of the property. When the right is not admitted, the entry has no effect, and the claimant must proceed by ejectment.

Entry, forcible, is an entry made with a strong hand, with unusual weapons, an unusual number of servants, or with menace of life. If effected with violence, and the entry only amounts in law to a trespass, it is not within the meaning of the statutes of Richard II. above referred to. The remedy for parties aggrieved, and the mode of obtaining restitution, is either by an action at law, by indictment, or by justices of the peace upon the view. If made by more than three persons, they may be proceeded against as in case of a riot.

Entry, the writ of, was the ancient method of gaining possession of disputed property by trying the title of the occupant. This writ was directed to the sheriff, requiring him to command the tenant that he render to the demandant the premises in question. The tenant thereupon was either compelled to deliver up the possession of the land, or to show cause why he refused to do so. This might be done by justifying his own title or that of others under whom he claimed. The claims of the respective parties were then tried before a jury, and the possession of the land was awarded to him who produced the clearest evidence of his right.

There were several writs of entry both at the common law and by statute, but they appear to have long fallen into disuse before their final abolition by the stat. 3 & 4 Will. IV. c. 27. The learning respecting them, which is somewhat curious, may be found in Reeve's

'History of the English Law.' (Blackst., 'Comm.,' Mr. Kerr's ed., v. ii., p. 191; v. iii. p. 183.)

ENVELOPE-MAKING. Until the introduction of the great change in the postal arrangements of the United Kingdom about twenty years ago, envelopes for letters were very little used. There was sufficient reason for this, seeing that double postage was charged for any letter consisting of two pieces of paper. The letters themselves were directed and sealed, or wafered, without exterior coverings. When, however, letters were charged only with a postage-rate by weight, the same obstacle did not exist; and it disappeared entirely when the penny rate commenced, whereby a moderately sized letter and its envelope could both be conveyed to any part of the United Kingdom for one penny. In 1839, just before these changes were made, the letters posted in or passing through the whole kingdom were about 76,000,000 annually; since which time they have risen to 523,000,000 in 1858, under the influence of cheapness and efficiency. The manufacture of envelopes has hence, become a matter of some importance; for nearly all letters are now enclosed in such covers, except certain official kinds. The number of envelopes actually made is not correctly known; for large numbers are used for purposes which do not bring them within notice of the postal authorities. The French used envelopes before they were much employed in England; and the Americans send over large quantities made of a peculiar kind of drab or buff paper; but the great proportion are of home production, and, in the present day, machine-made. At first, a hand-method was adopted for cutting, folding, and gumming. The sheets of paper were in the first place shaped by sharp cutters, acting against the edges of guide-plates, and penetrating several layers of paper at once. The shaped pieces were then folded, something in the same way as the sheets of paper for bookbinding; an expert worker could fold three thousand in a day, but not so uniformly and symmetrically as they are now folded by machine. The gumming, and the embossing on the loose flap, were subsequent operations. Envelopes are still made in this way; but there are no means of knowing what ratio they bear to those made by machine.

Although the extensive use of envelopes began in 1840, and the ingenuity of inventors was soon afterwards directed to the possibility of producing an envelope-making machine; it was not until 1851 that the public became familiar with the results. Messrs. De la Rue's envelope-machine was one of the most attractive objects at the Great Exhibition in Hyde Park—throwing off its three thousand envelopes per hour, and showing how much may now be effected by the labour of one or two persons. There was another machine exhibited, and many specimens of envelopes unaccompanied by any notice of the mode of manufacture; but the one above adverted to was that to which attention was most deservedly directed.

This highly ingenious machine, the joint invention of Mr. Warren de la Rue and Mr. Edwin Hill, was patented in 1845; and to it were made certain additions which were the subject of another patent in 1849. The paper is not cut to the proper lozenge or diamond shape by the machine itself, but by a cutting apparatus used separately. Nor does the machine feed itself with these blanks; it is fed by an attendant at the rate of about sixty a minute. When the blanks have been cut out, and embossed with any device that may be chosen, each one is placed in turn on a small table or stand. A compound box or plunger descends, presses the paper into a recess, and makes four creases in it, in such way that four flaps stand upright. Four folding levers, which act the part of fingers, then descend one after another, and fold the four flaps of the envelope. After the end flaps have been turned down, however, and before the side flaps are similarly treated, a gumming apparatus moves forward, and applies a little gum to those parts which are to be fastened together. This gumming apparatus is beautifully contrived; an endless band moves through a trough of gum or adhesive composition, takes up a portion and imparts it to a sort of printing-lever, which in its turn transfers the gum to the paper. When this is completed, the gumming apparatus withdraws, and the folding levers press down the remaining flaps of the paper. The automatic action of the machine instantly removes the finished envelope, to make way for another. To prevent the flaps from flying open again while the gum is yet moist, each envelope is transferred to the *bottom* of the heap already made, so as to receive pressure for a short time; two levers acting like fingers, tipped with india-rubber to render them slightly adhesive, draw the envelope sideways, and carry it to a point where an endless band takes it under a roller to receive a slight pressure, and then deposits it at the bottom of a previously made heap of envelopes, lifted up for that purpose. By a little adjustment of the mechanism, the folders can be adapted for envelopes of different sizes. As the feeding of the machine must be as rapid as the cycle of operations, any failure in it would produce mischief; if a blank were not deposited on the proper spot at the proper instant, the gum would wet the small table, and thus spoil the next envelope; and at the same time a disarrangement of the finished heap would take place. The attendant is provided with means for avoiding these two evils, without stopping the machine. One machine can make 30,000 envelopes in a day.

Another envelope-making machine, exhibiting great ingenuity, was patented by M. Rémond, in 1849, and was afterwards purchased by Messrs. Dickinson, to be used in their paper works at King's Langley. This machine is self-feeding. A hollow arm, moving backwards and forwards, is alternately exhausted and filled with air; in its exhausted state, it comes down gently upon a heap of paper blanks, one of which slightly adheres to it by a species of suction; the arm moves on, becomes filled with air, and drops the blank on a moveable table. The blank is then pressed against two pieces of sponge saturated with gum, by which it is gummed just in the right places for fastening. After this, the folding is effected by a combination of plungers and folding-levers. The machine is more automatic than De la Rue's in regard to the feeding, but not so much so in the pressing and final removal of the envelopes.

There are other envelope-making machines which have been patented, but which need not receive any lengthened notice here. Messrs. Pollard and Mumby's machine is intended to effect the feeding, gumming, stamping, folding, and delivering, all by the aid of one person. The blank is fed upon a folding-box, and gummed on the lower flap. At the same time it is embossed or stamped on the opposite or seal flap, and with the maker's name on one of the end flaps. A folding plunger then descends into the folding-box, driving up the edges of the paper into a vertical position; the plunger then rises; and spring incliners give the necessary inclination to the flaps. The plunger descends again, and presses down the flaps on the gummed surface. The envelope finally falls from the box upon a moveable bottom. Shaw's envelope machine was intended by its inventor as an improvement on Rémond's. It has an adhesive substitute for the pneumatic feeder, which takes the blanks one by one off the heap; this substitute is made of india-rubber treated with turpentine. There are also elastic revolving surfaces acting in conjunction with the plunger; four rollers covered with india-rubber form the sides of the folding-box; and a plunger drives the blank down between the rollers. In Addenbrooke's patented machine, an attendant places the blanks on a feeding-table, adjusts it by guide studs, and works a treadle. A complicated system of rollers, arms, excentrics, springs, levers, flies, screws, fingers, and plungers is set in action; a gum-box, gum-distributor, and gum-pad do one part of the work; after which, the creasing and folding are effected nearly in the same manner as in the machines already described. The envelopes are finally deposited on an endless band, which carries them away to a receptacle. Keith's envelope-machine, like most of the others, requires that the blanks should be fed in by hand; they are creased by the descent of a plunger into a creasing-box; a partial exhaustion of air then holds the paper in the box while the plunger rises. The box then advances to another plunger, for folding and pressing the flaps; this second box has projecting sliding pieces, which first turn down one of the flaps, and then lay the end flaps upon it. There is an air-exhausting apparatus connected with the plungers.

ENVOY, a diplomatic minister or agent, inferior in dignity to an ambassador, but generally invested with equal powers. [AMBASSADOR DIPLOMACY.]

EOS ('Ηώς), in Greek mythology, the Goddess of the Morning; the Aurora of the Romans. The daughter of Hyperion and Theia, and the sister of Helios and Silene, it was her task to precede the chariot of the sun, and announce the coming day. By Tithonus she was the mother of Memnon and Emathion. She urged Zeus to render Tithonus immortal; but having forgotten to ask that he should retain his youth, he at length withered away and she changed him into a cricket. She carried off Cephalus from Mount Hymettus, and became by him the mother of Phaëton, but eventually allowed him to return to his wife Procris. The splendour of Eos, or Aurora, was a frequent theme of the Greek and Roman poets. She was also a favourite with the ancient artists. There are many representations of her both in sculptures and on vases. The carrying off of Cephalus occurs frequently. Sometimes she is represented in a magnificent quadriga; at others guiding the horses of the sun; or again preceding or pursuing Orion.

EPACT, the number of days in the moon's age at the beginning of the year.

EPAULEMENT is the term properly applied to the mass of earth, about 7 feet 6 inches high and 18 or 20 feet thick, which is raised for the purpose of either protecting a body of troops from the enemy's fire, or of forming a wing or shoulder of a battery to prevent the guns from being dismounted by an enfilading fire. It is in fact the term applied to many works of merely passive defence. The term is occasionally, improperly however, used to designate the whole mass of earth or other material which protects the guns in a battery both in front and on either flank; and it can only be distinguished from a parapet by being without a banquette, or step, at the foot of the interior side, on which the men stand to fire over a parapet. That part of the epaulement which is between every two embrasures is called a merlon; and the part under the embrasure is called the genouillère.

EPHEMERIS (*ἐφημερίς*, from *ἐπί*, and *ἡμέρα*) a name given to almanacs, from their containing matter for each day. In astronomy it is usual to call any table which assigns the place of a planet for a number of successive days an ephemeris of the planet. [ALMANAC.]

EPHESIANS, ST. PAUL'S EPISTLE TO THE, is the fifth, in numerical order, of the fourteen apostolical letters of St. Paul, contained in the canon of the New Testament. Throughout the primitive ages of Christianity it was regarded by the principal fathers as being of genuine and sacred authority. According to Dr. Lardner ('Credibility of Gosp. Hist.,' vol. ii.) the writings of Ignatius, who was St. Paul's contemporary, contain seven citations from this epistle. It is also cited by Irenæus, Clemens Alexandrinus, Tertullian, Origen, and many subsequent Christian writers. There were, however, several important and numerous sects, as the Nazarenes or Ebionites, and the Severians, Encratitæ and other followers of Tatian, who, in the 1st and 2nd centuries, denied both the genuineness and the authenticity of this and the other writings of St. Paul; rejecting them as a tissue of errors, and denouncing St. Paul himself as an apostate, and a perverter of the original system of Jesus of Nazareth. (Origen 'contra Celsum,' l. v.; Euseb. 'Eccles. Hist.,' l. iii., c. 21 and 27; Epiphanius, 'Hæres.,' 30; Hieron. 'in Math.,' c. 12; Nicephorus, 'Hist. Eccles.,' l. iv., c. 4, l. v., c. 12; Toland's 'Nazarenus,' p. 25–29.) A second epistle of St. Paul to the Ephesians is mentioned by Jerome ('De Scriptoribus Eccles.') and by Epiphanius ('Hom.' 42). The place and date generally assigned to this epistle by biblical critics are Rome, A.D. 61, that is, in the first year of the apostle's imprisonment at Rome (ch. iii. 1, ch. iv. 1, ch. vi. 20, and the postscript). Much has been written by commentators for and against the opinion that St. Paul addressed this letter to the Ephesians. The belief that it was so written is founded on the disputed reading of the words of the first verse, "to the saints at Ephesus" (ἐν Ἐφέσῳ), which appear in all the ancient manuscripts, and on the postscript which says, "written from Rome unto the Ephesians." This however is doubted and denied to be the fact by Grotius, Hammond, Mill, Wetstein, Paley, and Greswell, who adopt the statement, said by Tertullian to have been made by Marcion, that it was written to the Laodicæans. Macknight, Lardner, Hartwell Horne, Dr. W. L. Alexander, and Barnes (in his 'Commentaries'), see no difficulty in believing it to have been addressed to the Ephesians, and so far to establish the common opinion of the received reading of the introductory verse, addressing the epistle to "the saints in Ephesus." Of the same opinion is Dr. John Eadie, in his 'Commentary on the Greek Text of the Epistle of Paul to the Ephesians' (London, 1853); while Conybeare and Howison believe it was not addressed to the Ephesians. Archbishop Usher considered it a cyclical epistle addressed to no particular church, but to all, though Ephesus might have been the chief; and this opinion is advocated by Bengel, Michaelis and Hug. The style is exceedingly animated and fluent, and has less metaphorical obscurity than generally characterises the compositions of St. Paul; though from the length of the sentences, the number of members in each sentence, and the want of or imperfect punctuation, the original is often capable of more than one interpretation. It is also noticeable that, though St. Paul had resided so long, and was so well acquainted with the members of the church, in Ephesus, he addresses no one by name, but writes as if he were addressing persons unknown to him. The object appears to be to establish an earnest faith in the doctrines of Christianity, by giving exalted notions of their importance and moral excellence, and to encourage a perseverance in the Christian warfare with temporal and spiritual enemies. The first three chapters are occupied in especially setting forth the principles of predestinarianism (i. 4, 5, 11, iv. 30), and the last three are devoted chiefly to the enjoining of moral duties with respect to husbands, wives, parents, children, masters, and servants. "No real Christian," says Dr. Macknight, "can read the doctrinal part of this epistle without being impressed and roused by it, as by the sound of a trumpet." On the undesigned coincidences with the 'Acts' see Paley's 'Horæ Paulinæ.' The moral and doctrinal precepts of this epistle, with respect chiefly to election, have occasioned theological critics, especially those of Germany, to write elaborately on its proper interpretation.

E'PHORI (ἔφοροι), a body of magistrates at Sparta, who were possessed of great privileges. The institution of this office is usually ascribed to Theopompus, the grandson of Charilaus the Proclid, but from their being apparently placed among the institutions of Lycurgus by Herodotus (i. 65) and Xenophon ('de Rep. Lac.,' viii. 3) the office has been considered by some as a Dorian institution. Mr. Grote however ('History of Greece,' vol. ii.) contends that the institutions of Sparta were altogether peculiar to herself, and in no respect characterise the Dorians. Dr. Arnold supposes ('Thucyd.,' vol. i. p. 646) that the ephori, who were five in number, were coeval with the first settlement of the Dorians in Sparta, and were merely the municipal magistrates of the five hamlets which composed the city (see Müller, 'Dorians,' ii. p. 550, Engl. transl.); but that afterwards, when the Heraclidæ began to encroach upon the privileges of the other Dorians, and, it would seem, in the reign of Theopompus, who endeavoured to diminish the powers of the general assembly of the Spartan aristocracy, the Dorians, in the struggle which ensued, gained for the ephori an extension of authority which placed them virtually at the head of the state, although the nominal sovereignty was still left in the hands of the Heraclidæ. Thus the ephori were originally popular magistrates as far as the Spartans themselves were concerned, and were in fact the guardians of their rights from the encroachments of the kings, though they were in relation to the Periœci (περίοικοι) the oppressive instruments of an overbearing aristocracy, and formed in fact a close and unscrupulous oligarchy. (Plato, 'Legg.,' iv. p. 712 D.') The ephori were chosen in the autumn of every year; the first gave his name to the year; every Spartan was eligible to the office without any regard to age or wealth. They were empowered to fine whom they pleased, and exact immediate payment of the fine; they could suspend the functions of any other magistrate, and arrest and bring to trial even the kings. (Xenophon, 'de Rep. Laced.,' viii. 4.) They presided and put the vote in the public assemblies (Thucyd., i. 87) and performed all the functions of sovereignty in receiving and dismissing embassies (Xen. 'Hellen.,' ii. 13, 19), treating with foreign states (Herod., ix. 8), and sending out military expeditions. (Xen., 'Hellen.,' ii. 4, 29.) The king, when he commanded, was always attended by two of the ephori, who exercised a controlling power over his movements. (Herod., ix. 76.) The ephori were murdered on their seats of justice by Cleomenes III., and their office overthrown (Plutarch, 'Vit. Cleomen.,' c. viii.); but they were restored by Antigonus Doson and the Achæans in 222 B.C. (Polyb., ii. 70; Pausan., ii. 9, 2); and the office subsisted under the Roman dominion. When Lysander with the Spartan forces made himself master of Athens, B.C. 404, Ephori were appointed for that city, among whom were Critius and Theramenes, but these soon gave way to the domination of the thirty tyrants. (See Böckh, 'Corpus Inscriptionum,' i. p. 604-613.) On the ephoralty, the reader may consult Müller's 'Dorians,' book iii.; Plass's 'Geschichte des alten Griechenlands,' vol. ii.; Tittmann's 'Darstellung der Griech. Staatsverfassungen;' and Grote's 'History of Greece,' vol. ii.

EPIC POETRY is that form of art which produces an imaginative description of external facts and occurrences, as distinguished from lyric poetry, which employs itself in registering, in an imaginative manner, all those internal facts and occurrences which go by the name of feelings and emotions.

Those who find this definition insufficient must remember that it does not and is not intended to apply to any single epic or lyric poem. With the exception, perhaps, of some of our old national romances, there does not exist an epic poem of any length which is perfectly free from lyrical passages; but this is no reason why we should confound the two forms of art, and not assign to poetry the one name or the other according to the proportion which it contains of either element.

From what we know of the operations of our own minds, and of the analogy which subsists between the growth of individual and national intellect, it appears most natural that epic should be the earliest species of poetry. A child, born into a crowd of circumstances all claiming his attention and exciting his interest, busies himself with the external world long before it ever occurs to him to examine what is going on within himself. Nay, more than this, his imagination, the idealising faculty, takes the models of its exertions entirely from the external world. His dreams, his reveries, his waking fancies, are active and epical, as any one who has watched the movements of children must acknowledge; but the time when he begins to notice his own thoughts and feelings—the lyrical age—does not come till later.

The earliest specimens of the epic form of art, which probably consisted of tales rhythmically arranged and recited to a very simple musical accompaniment, no doubt belonged to the unconscious era, during which the poet, setting before him no aim, or seeing it at best but very imperfectly, acts purely from the stirring impulse of his own imagination. Into this class we may perhaps admit some of our oldest and simplest romances; but the poetry of Homer and Hesiod, the twofold epic of the Greeks, cannot be denied to be, in great measure at least, the work of conscious artists. We shall notice the writings of the early Greeks first in order; and as it would swell this article to an unnecessary length were we to examine in detail the principal epic poems which we possess, we shall confine ourselves, in a great measure, to those which were composed during the periods both of ancient and modern history, when epic poetry could be said to be the poetry of the age, and leave those detached productions which owe their existence to the imagination of isolated men, in times long after the disappearance of the living epos, for a separate examination.

There are two divisions into which the epic poetry of the Greeks naturally falls; the heroic or romantic epos of Homer and of the Cyclic poets, and the hieratic epos of Hesiod. The attention of that age was centred, as ours is at present, on two grand ideas—the state and religion; whence we find a political and a hieratic epos. The 'Iliad' and 'Odyssey' are the two poems which remain as specimens of the former kind, and they are particularly worth the attention of all who are interested in the history of epic poetry, as they afford by far the most perfect instance of poems of that kind composed in an age differing but little in its characteristics from that to which they refer, and stand consequently in strong contrast to the 'Æneid,' a poem with which they are most frequently compared. The 'Æneid,' in common with most Latin poetry, depends more on beauty of language and arrangement than on anything in the story, exquisitely managed as it is, to excite the interest of its readers. As it traces the life of an individual, it stands in closer juxtaposition with the 'Odyssey' than with the 'Iliad;' but how superior is Ulysses to Æneas, and how much more romantic are the adventures of the Greek than those of the Trojan hero!

Perhaps there is not in the whole compass of literature a more perfectly drawn character than Ulysses, certainly none proceeding from so early a source. His touching exhibitions of feeling, the inimitable circumstantiality of the fictions which he spins in such profusion, apparently for no purpose except to confound his auditors; the manner in which all the interest of the story winds around him, the comic nature of the interludes, and the peculiarities attaching to the supernatural parts of his adventures, all unite to render the 'Odyssey' a poem more fitted perhaps than the 'Iliad' itself to interest an age like ours, when everything which gives a lyrical character to poetry is so much although so unconsciously sought for.

It usually happens that sacred poetry partakes strongly of a lyrical character, and Hesiod has perhaps struck out the only path which an epic writer in a simple age could follow without lapsing into the lyrical spirit as he approached theological subjects. The only poet of antiquity with whom he can be compared is Lucretius; but the 'De Rerum Naturâ' approaches so much more nearly to the character of a treatise on philosophy, that it is hard to give it the name of an epic poem, although it, as well as all didactic works like Virgil's 'Georgics,' come under the definition. The reason why we are slow to recognise them as epics arises from the habit of taking the heroic epos, one species, although the primary one, for the whole class, which really includes other species, as a reference to our definition cannot fail to show.

It has been observed by a German writer (Schelling, 'Vorlesungen,' &c., p. 224) that, properly speaking, an epic poem has no regular beginning or end; it is a metrical and imaginative production, which, if it consist of narrative, may take it up and lay it down at any period. This is the case with the Iliad, as well as with the Odyssey and Æneid, although the two last are considerably more complex in the arrangement of the narrative, and evidently draw to a more decided close than the Iliad. There appears, however, to be a greater unity in the plot of the Odyssey than in that of Virgil's poem, in this respect, that the events never get the upper hand of the hero. We are interested in his adventures because they are his; while in the Æneid they strike us rather as embellishments intended to possess independent merit.

The early romantic epos deserves notice as the first distinct form of modern art. Much discussion has been expended in order to ascertain whence arose those cycles of metrical romances which have for their subjects the exploits of Alexander the Great, King Arthur, and other heroes; but it rather concerns us here to notice that the second birth of civilisation which ensued on the breaking up of the Roman empire was productive of a series of events in literary history, parallel, as far as we can judge, to those which occurred in the times of Homer.

The traces of heroic poetry which remain in Livy's History are plain enough to enable us to infer with considerable probability that a series of epic poets appeared in Rome about the time of the Tarquins onwards; but as no fragments remain, we are too much in the dark as to the nature of their writings to enable us to refer to them as we do to Homer.

We find that the northern nations possessed numerous poems of an epical kind, some of which remain, and are or might be read with considerable interest. The cycles of romances on Troy and Alexander the Great compose a form of art which could only exist in a revival of imaginative spirit, as they derive their subjects from an older date and a different country, although, as regards every thing but the name of Greek or Trojan, the hero is usually the countryman of the bard; but the numerous poems on Arthur, with 'Havelok the Dane,' and 'Horn Child,' in our own language, 'Beowulf,' in Anglo-Saxon, 'The Poem of the Cid,' in Spanish, and the 'Nibelungen Lied,' in old German, are quite sufficient proofs of the coincidence of epic spirit with an early stage of society.

The Italian epic arose somewhat later than that of any of the northern nations, which may be attributed to the fact that it was only to a strong admixture of barbarian blood that the Italians owed their restoration to political existence. The dregs of a nation never possess a national literature.

Coleridge has observed that "Gothic art depends on a symbolical expression of the infinite," or what cannot be circumscribed within the limits of actual sensuous being, while in ancient art everything was finite and material. ('Lit. Remains,' vol. i. p. 68.) This applies more directly to architecture, but in a measure also to literature, although we think that the introduction of Christianity had more to do with it than the cause which Coleridge assigns, namely the wild liberty of the Northman's habits and manners and the imagery of nature which surrounded him. Perhaps the greatest difference which is traceable between the ancient and the modern epic has been produced by that spirit of devotion to the female sex which characterises all the Gothic nations; and arising as it does, partly from the refinement of an instinct and partly from religious impressions, is very superior, as a motive of action, to the mere unmitigated instinct for war which constitutes the prevailing feature of the ancient epic, or at least of the heroic poems.

We have been at no pains to notice those detached epic poems which have appeared at different times since the revival of learning, although some of the most noble specimens of this style of poetry are to be numbered amongst them; still less have we intended to give anything like sketches of any which we have mentioned, as this is properly done under the heads of the several authors, in Biog. Div.

EPICHLORHYDRIN. [Chlorhydrin.]

EPICYCLE, a circle, the centre of which is carried round upon another circle: a term of the Ptolemaic System.

EPICYCLOID. [Trochoidal Curves.]

EPICYCLOIDAL TEETH OF WHEELS. [Wheels, Teeth of.]

EPIDEMIC (*ἐπιδήμιος, epidémius*; from *ἐπί*, in the sense of "over" "all through," and *δῆμος*, "people") diseases are those which prevail among a large portion of the people of a country, rage for a certain time, and then gradually diminish and disappear, to return again at periods more or less remote. Thus cholera and influenza have prevailed as epidemic diseases in this country; and the continued fevers called synochus and typhus, and what are termed the eruptive fevers, as scarlet fever, the small-pox, the measles, frequently prevail as epidemics in different parts of the country. It is essential to the medical notion of an epidemic disease that it be dependent on some common and widely-extended cause, of a temporary in contradistinction to a persistent nature. [Endemic.]

EPIDERMOSE. [Fibrin.]

EPIGRAM (*Ἐπίγραμμα, Epigramma*; from the Greek *ἐπί*, *on*, and *γράφειν*, *write*), in its proper sense, is—a writing on—an inscription; whence it comes to signify a short poem, such as might be comprised within the limits of an inscription. For an account of the class of poems called epigrams by the Greeks, see Anthology; they are dedicatory, descriptive, amatory, elegiac; rarely humorous or satirical; and their merit consists "in the justness of a single thought, conveyed in harmonious language." (Preface to Bland and Merivale's 'Anthology.') Much of early Greek history was preserved in epigrams, to which Herodotus and Thucydides often refer; as for instance, those concerning the battle of Thermopylæ (Herod. vii. 228), one of which is thus literally translated: "Here once four thousand from Peloponnesus fought with three millions."

The Latin epigram approaches nearer to the English acceptation of the term, being much oftener dependent for its merit upon humour and personality. The most distinguished Latin epigrammatists are Catullus and Martial, in whom there is much wit, disfigured by much scurrility and obscenity; but many of the epigrams of Martial are epigrams in the Greek sense, and some of them are characterised by a propriety of thought and felicity of expression that could not easily be surpassed. The Latin Anthology of Peter Burman the younger contains a large collection of epigrams, by numerous authors, of which many resemble in simplicity the Greek epigrams.

In English the word signifies a short poem, which, to be good in its kind, must be clear, concise, and elegant in expression, and must contain a point, that is, some striking and unexpected turn of thought; whether it be humorous or serious is indifferent. The following terse and elegant compliment addressed by Pope to Lord Chesterfield, on being asked to write with that nobleman's pencil, may serve as well as any for a specimen:—

> Accept a miracle; instead of wit,
> See two dull lines by Stanhope's pencil writ.

EPILEPSY, *Epilepsis* (*ἐπίληψις*), 'a seizing.' Synonymes: *Morbus divinus, herculeus, comitialis, caducus*; *Falling Sickness*. Sudden abolition of sensation and consciousness, with convulsions [Convulsion] of the muscles of voluntary motion, ending in a state of sopor or apparent sleep, the attack recurring in paroxysms more or less regular. The attack of epilepsy is usually quite sudden. The person, while in his ordinary health, and perhaps engaged in his usual occupation, utters a piercing scream. If standing, he falls to the ground, where he lies for a moment in a state of extreme rigidity, almost amounting to tetanic stiffness; but this state is quickly succeeded by convulsions, which variously agitate the limbs and the trunk of the body. The head is generally thrown backwards; the eyes are open, fixed and staring; the pupils are dilated; the vessels of the head and neck are swollen, rendering the countenance flushed, and sometimes of a dusky hue; the muscles of the face are in violent action, producing frightful distortions of the countenance; the muscles that move the lower jaw close the mouth with violence, producing gnashing of the teeth; the tongue, which is swollen and livid, is thrust out forcibly between the teeth, and is often grievously wounded; the arms are sometimes tossed violently about the chest, or struck against it; the hands and fingers are in a state of rapid alternation, between the motions of flexion and extension; the lower extremities are agitated in a similar manner; the thumbs are drawn inwards, and the toes incurved: and a quantity of frothy saliva flows from the mouth, which is often bloody from the wounds inflicted on the tongue. The muscles on one side of the body are commonly more violently agitated than those of the other. Several cases are on record in which the muscular contractions were so violent that the bones of the limbs were broken, the teeth fractured, and the joints dislocated. Generally the convulsions have for a few moments some remission, when they are again suddenly renewed with great violence. The breathing is disordered in consequence of the convulsion of the muscles of respiration. At first heavy and difficult as if a load were placed upon the chest, it becomes at length quick, short, irregular, and stertorous, and is often accompanied with sighing and moaning. The diaphragm, the muscles of the abdomen, and the muscular fibres of the bladder, contract with so much violence that the fæces and the urine are discharged involuntarily and with great force.

The pulse, always difficult to be felt, is commonly quick and small but it becomes distinct towards the end of the paroxysm, and is then more slow and languid. The action of the heart is irregular, tumultuous, and loud, and the carotids throb vehemently. After the contractions of the muscles have continued for some time the convulsions diminish in violence, and at length cease altogether. Perspiration breaks out about the head, neck, and breast; the convulsive respiration is followed by sighs, and the spasms of the muscles by subsultus. The patient is now restored to a slight degree of consciousness; but, as if exhausted by the violence of the struggle, he soon sinks again into a state of profound insensibility, and lies in a deep sleep. During the state of sleep, the perspiration becomes copious and general over the whole body; the pulse fuller, softer, and slower, and the respiration freer and easier. After a time the person awakes, sometimes suddenly, but in general it is only by degrees that sensation, consciousness, and the power of motion return. Commonly there is no consciousness whatever of anything that has passed during the paroxysm. On coming out of the fit there is generally headache, and always languor. The convulsive stage may last from one or two minutes to fifteen or twenty, and the sleep from one to several hours. The duration of the whole paroxysm is generally from five to ten minutes; but often two or three attacks follow each other in such rapid succession, that the paroxysm seems to be protracted for several hours. Occasionally death takes place unexpectedly in the midst of the fit, either in consequence of injury inflicted on the brain by congestion of the cerebral blood-vessels, or by the suspension of the respiration through the spasm of the muscles of the larynx, which close the opening of the glottis so completely and for so long a time as to induce the state of asphyxia.

Such are the general circumstances which accompany an epileptic attack, and the general form of the disease is pretty much the same in all the persons afflicted by it; the chief difference is in the slightness or severity of the phenomena, in which there is every possible variety, from an attack so severe as to produce instantaneous death to one which is so slight that it can scarcely be perceived. Sometimes, for example, instead of the regular and violent fit just described, the seizure consists merely of loss of consciousness, slight rigidity, spasms or convulsions of a few muscles or of a single limb, the attack lasting only a minute or two. At other times the patient is seized with sickness or a sensation of faintness, the sight becomes dim, the recollection imperfect, and the power of voluntary motion so far impaired, that the person slips from his chair, or falls from his horse, and lies on the ground insensible, pale, perspiring, but without convulsions. Or the attack may be so slight that consciousness is not wholly lost; but the mind becomes confused, the power of articulation suddenly diminished, and instead of finishing the sentence he was uttering, the person continues to mumble for half a minute or a minute the last words he was attempting to speak, in a slow, monotonous, gibbering manner; and then recovering, he takes up the thread of his discourse, being soon aware of an interruption of consciousness, which interruption there is often an effort to conceal. This state is described by the persons subject to it as one of great mental distress and depression, like a frightful dream: they feel perplexed and afflicted by an imperfect reminiscence of some overwhelming calamity, or a sense of remorse for which they cannot assign a cause. A paroxysm of this kind is like a short mood of extreme melancholy, and such is the impression that the countenance of the patient, which is full of sadness, makes upon the spectator. These slighter paroxysms may recur only at very distant intervals; but they more commonly return often, and sometimes three or four times a day.

The return of the regular epileptic paroxysm is exceedingly various in different individuals. Several years may intervene between the seizures; or they may recur once every month, week, or day. It is stated that they sometimes recur periodically, and with remarkable exactness to the very day; once a year, or once a month. When they recur monthly, and observe a stated day, that day sometimes coincides with the new or full moon, a coincidence to which great importance was attached in former times. The interval of a lunar month is more commonly noticed among females, from the connexion of the disease with the uterine functions. In some instances, the paroxysms occur every week, on the same day; and occasionally every day, or night, at the same hour; but they most frequently come on when first falling asleep, and are often for a time unsuspected or overlooked. Sometimes several slight seizures take place in one day; but their recurrence is often extremely irregular. When they are neglected, they usually either become more and more severe, or occur after shorter intervals. Consciousness and sensation being abolished, pain cannot be felt during the fit.

Though the epileptic attack usually comes on suddenly, yet it sometimes gives distinct warning of its approach. The symptoms premonitory of an epileptic fit are analogous to those which precede an attack of apoplexy [Apoplexy], namely, headache, giddiness, flushing of the face, throbbing of the temples, drowsiness, sense of weight or heaviness of the head; flashes of light before the eyes, sleeplessness, fretfulness, irritability, or unusual cheerfulness and hilarity; disorders of the digestive organs, as voracious appetite, sickness, vomiting, constipation, or diarrhœa. But there is one peculiar sensation, termed the *aura epileptica*, of which many epileptics are conscious immediately before the fit. This consists of a feeling as if something were moving in some part of the limbs, or trunk of the body, and creeping thence upwards towards the head. Sometimes it is described as a sensation of a current of air, a stream of water, or a slight convulsive tremor; at other times no distinct idea can be given of the feeling further than that it is a sensation of something moving along. This remarkable sensation does not appear to follow very distinctly the course of a nerve, but it seems to pass along the integuments. When it reaches the head, the patient is instantaneously deprived of sense, and falls down in convulsions. The sensation arises in different parts of the body, in the toe, foot, leg, and groin; in the finger, hand, and arm; at the bottom of the spine; in the uterus, loins, abdomen, and chest. But, in the great majority of cases, the attack of epilepsy is preceded by no such warning; and even where the premonitory symptoms do exist, the attack does not by any means always follow.

Epilepsy rarely occurs in a person otherwise in sound health. Out of three hundred cases, the early history of each of which was carefully investigated, very few had been perfectly well previously to the accession of the disease. Convulsions during the first dentition, eruptions on the skin, mental excitement, diseases of the glands, chorea, hysteria, tremor, cramp, vertigo, palpitation, headache, flushing, bleeding from the nose, precede the first epileptic attack, and perhaps may be considered, at least in part, as predisposing causes of the malady.

As this disease is often long preceded by other maladies before the actual seizure, so, after it has subsisted for some time, it induces a peculiar state of the constitution, and more especially, it would appear, in the nervous system, which predisposes to the recurrence of the attack, and the signs of which internal state are manifest in a peculiar expression of the external features. The eyelids become swollen: the eyes prominent and unsteady; the look vacant; the cheeks pale, the lips thick; and the individual features, however originally beautiful, grow coarse, and lose their fine expression. The steadiness and energy of the mind progressively diminish; the purpose becomes irresolute, and the power of continuous application for the accomplishment of a given object is lost. Instances are recorded in which, though the disease recurred frequently for a long series of years, neither the memory nor any other mental faculty appeared to be impaired; but this is exceedingly rare.

"Of 298 epileptics in the Salpêtrière, in 1813, 80 were maniacal, and 56 in various states of mental alienation and imbecility. In 1822, out of 339 cases in the same hospital there were 2 monomaniacs, 30 maniacs, 34 furious maniacs, 129 insane for some time after the paroxysms, 16 constantly insane, 8 idiotic, 50 upon the whole reasonable, but with impaired memories, and liable to occasional slight delirium and tendency to insanity, and 60 without aberration of intellect, but irascible, capricious, obstinate, and presenting something singular in their characters." A very common termination of epilepsy is apoplexy or paralysis.

Authors commonly divide epilepsy into two species: first, idiopathic, where the disease depends on some primary affection of the brain, and, secondly, sympathic, in which it depends on an affection of some remote part, as the stomach, the liver, the bowels, the generative organs, the circulating system, &c.

The state of the brain on which epilepsy depends is unknown. Dissection shows that the brain of the epileptic is seldom sound; but much as this subject has been investigated, little light has hitherto been shed upon the pathology of the brain as connected with this disease. The most common morbid appearance are the thickening of the bones of the skull; spiculæ or morbid growths of the bone from the inner table of the skull; vascular turgescence, or inflammation of the membranes of the brain; preternatural hardness or softening of the substance of the brain and of the spinal cord; effusions of serum, blood, jelly, or pus between the membranes, upon the surface or into the ventricles of the brain; tumors or morbid growths in its substance; adventitious deposits, as tubercles, or parasitic animals, as hydatids. Recent researches appear to indicate that the parts of the brain which most commonly undergo morbid changes of structure in this disease are the parts more immediately in the neighbourhood of the sphenoid bone, and especially the pineal and the pituitary glands, and particularly the latter. But occasionally, where violent epilepsy has existed during life, the most careful examination of the brain after death has led to the discovery of no appreciable change in its structure; while even the morbid appearances which are manifest are often observed to be present without being accompanied with epilepsy; so that the relation between any known morbid change in the structure of the brain and epilepsy is not yet certainly established. It follows, as has been stated, that nothing is really known of that condition of the brain which causes epilepsy.

But many of the causes of the malady are well ascertained, and the knowledge of these is of great importance in the prevention and cure of the disease. It is conceived that there is a constitutional predisposition to epilepsy, although it does not seem easy to assign with exactness in what this predisposition consists. Several of the exciting causes are weak impressions which are applied to most persons with little or no effect.

The exciting causes consist of two classes, those which act by exciting the energies of the brain, and those which act by depressing the brain. Those which act by over-stimulating the brain are mechanical, chemical, and mental stimulants, and the peculiar stimulus of over-distention; as sharp-pointed ossifications, arising either from the internal surface of the cranium or formed in the membranes of the brain; powerful mental emotions, such as joy and anger; congestion of the blood-vessels of the brain; suppressed discharges; violent exercise; too large a quantity of highly nutritious food or of stimulating drink. "I have observed," says Fothergill, "that epileptics are often extremely incautious with respect to diet; that children highly indulged are liable to the disease; that in every other period of juvenescence, and in middle-aged adults, if they were attacked with the disease, it was when they had either committed some excesses or by one means or another were plethoric, and that in habits subject to epilepsy, the disease seldom recurred without either an habitual indulgence in eating or a neglect of necessary exercise."

But the very opposite causes, those which manifestly weaken the energy of the brain, occur in epilepsy, as hemorrhage, whether spontaneous or artificial; terror, horror, disgust; any powerful and disagreeable sensations, and especially certain disagreeable odours; excessive evacuations, great fatigue, inanition, and sedative poisons.

The medical treatment of a case of epilepsy must of course differ essentially according as it is idiopathic or sympathic, and connected with a plethoric and robust, or debilitated and exhausted state of the system. Unless he previously ascertain the condition of the brain and spinal cord, or the nature of the affection of the remote organ in sympathy with which the brain is suffering, the practitioner must work entirely in the dark, and must be liable to adopt the very opposite course of treatment to that which the case really requires. When the appropriate remedies are judiciously employed, and the proper regimen is strictly adhered to, epilepsy is often permanently cured, and the suffering is greatly mitigated even in those forms of the disease which do not admit of cure. Dr. Cheyne has laid down some excellent rules for the management of epileptic patients, of which, as they are of a popular nature, and applicable to the great majority of cases, we give the substance.

In prescribing a rule of diet suitable to all epileptics, moderation in quantity and simplicity in the preparation of the food are indispensable points. The diet best calculated to preserve an individual liable to scrofula from an attack of that disease is best suited to a patient liable to epilepsy. Fermented liquors should in general be altogether withheld. Flesh-meat ought to form the principal part of one if not two meals in the day; and milk, if it do not retard digestion, which it is less liable to do when fermented liquors are laid aside, is the article next in value. The epileptic ought to be trained so as to be in good wind, so as to put his muscles in a state of the utmost strength and firmness. Epileptics should be put under a regular course of training like the athletæ of ancient, and the gentlemen of the fancy in modern times. When the patient leaves his bed in the morning, he may have a rusk or a slice of toasted bread with an egg beat up in a teacup full of warm water; then let him dress, make all needful arrangements, and walk three or four miles. Two hours or more after he has left his bed, let him have his second meal, milk or cream in water, or cocoa with bread a day old and butter. Rest for three hours after breakfast. This will be the best time to devote to business or education. Then he must again walk, if an adult possessed of sufficient vigour, from five to eight miles. At from five to six hours after his second meal, let him have a third, consisting of meat of the best quality, mutton, poultry, game, or very tender beef, roasted or boiled, of which an adult must not eat more than six ounces; bread, and one moderate helping of tender well-boiled vegetables; of drink, not more than a common tumbler full of distilled water, Seltzer water, with a little milk, or toast and water. Then rest for two hours; that is, stroll in a garden, read an amusing book, or engage in any occupation which will not raise the pulse by one beat; then resume more active exercise for an hour or two. In five or six hours after dinner, a light supper may be taken, consisting of not more than four ounces of meat with bread, or of a cup of milk with a water biscuit. The rest of the evening may be spent in cheerful society, in a large airy room, not over lighted nor over heated, but sufficiently warm to prevent that chill which in the latter part of the day often follows very active exercise; and every occupation by which the mind is depressed or is excited, and thereby subsequently exhausted, must be avoided. The patient must be in bed at eleven and up at six, nothing in general being more hurtful to epileptics than sleep unnecessarily prolonged.

The scalp in all epileptics ought to be shaved once a week, and daily well rubbed with a flesh-brush after the tepid shower bath, or what answers nearly as well, after pouring a flagon of tepid water on the head inclined over a large basin. The patient may gradually bring himself to sleep without a night-cap and without curtains, with the shoulders and head raised and the feet well protected from the cold, in a chamber as large and airy as possible and without a fire.

A patient liable to epilepsy must not be permitted to ride nor to hold the reins in a carriage. The grates in all the apartments which he frequents ought to be guarded by a deep and strong fender; he ought to avoid the streets of a crowded city, in which the whirl of carriages, the tide of human beings, and the multiplicity and distraction of objects produce a vertiginous hurry of thought, which to him is ever dangerous. He ought not to walk near water. A fine young man of twenty came to an untimely end in his own garden, by falling into a runnel, in which he was drowned, although the water was not more than four inches deep.

If an attack of the disease come on while the patient is in his chamber, he ought immediately to be laid on his back on a bed, with an attendant standing on each side to prevent him from injury during the struggle. If he is much flushed, his head and shoulders ought to be elevated, the warmth of his extremities supported, while at the same time air is freely admitted into the room. All attempts to make him swallow or to stimulate the nostrils are improper. A medical practitioner ought to be sent for, and ought to remain in attendance while the struggle lasts. In a first attack, if the fit is severe, blood ought to be procured from the temporal artery, a precaution which will also be necessary in patients of an apoplectic diethesis whensoever they labour under a prolonged fit of apoplexy.

(Cheyne, *Cyclopæd. of Pract. Med.*; Copland, *Dict. of Pract. Med.*; Prichard, *Diseases of the Nervous System*; Cooke, *Hist. and Method of Cure of the various Species of Epilepsy.*)

EPILOGUE (*ἐπίλογος, epilogus*) compounded of *ἐπί, on* or *after*, and *λόγος, speech*) signifies, in Greek, a summing up, the end or peroration of a discourse. In English it is applied to the short poems or copies of verses, or to the short prose address which formerly were commonly subjoined to new plays, and recited on the stage at their conclusion. An epilogue is usually written in a lively tone, with such allusions to the play, the author's circumstances, the news or fashions of the day, or other subjects of existing interest, as are thought likely to conciliate favour and send the audience away in good humour. "If it be true that good wine needs no bush, 'tis true that a good play needs no epilogue: yet to good wine they use good bushes, and good plays prove the better by the help of good epilogues." ('As You Like It.')

EPIPHANY, from the Greek *'Επιφάνεια* (*Epiphancia*), appearance, or manifestation, a church festival, celebrated on the twelfth day after Christmas, in commemoration of our Saviour's being manifested to the world by the appearance of a miraculous star; likewise denominated Twelfth Day. This day is said to have been first observed as a separate feast in the year 813. The customs of this day, though various in different countries, all agree in the same end, namely, to do honour to the eastern magi, or kings, who visited and made offerings to our Saviour at his birth.

EPIPOLIC DISPERSION OF LIGHT. [DISPERSION.]

EPISCOPACY. [BISHOP.]

EPISODE (*ἐπείσοδος, epeísodos*). The Greek word *eísodos*, the principal member of this compound, when applied to the drama, means an entrance of the chorus on the stage; *epeisódion*, that part of a play which lies between two choral songs; and as these recitations had, in the rude beginning of the Greek drama, no connection with the choral part, which they were introduced to relieve, the word, with its derivative Latin form, comes to signify a thing connected with, but not essential to, that of which it is part,—which may be taken out and leave a perfect work; as, for instance, the Catalogue of Ships, in the 'Iliad,' or the War in Heaven, in 'Paradise Lost.' Episodes should grow naturally out of the subject; and when judiciously used, they relieve and diversify the main narration. But they should be sparingly introduced, so as not to create confusion. In the 'Orlando Furioso,' for instance, or the 'Fairy Queen,' the episodes are so many and so long, that the whole resembles a set of detached legends inartificially patched together, rather than a single poem pervaded by one intention. Episodes are commonly the most highly-finished portions, since their shortness warrants a degree of elaboration and ornament which could hardly be maintained through a long composition, and indeed might be wearisome if it could.

EPISPACTICS. [BLISTERS.]

EPISTAXIS (from *ἐπίσταξις*, a dropping, bleeding of the nose) is the term used by most nosologists to indicate bleeding from the nose, which essentially consists in an effusion of blood externally from the pituitary membrane. There are few parts of the body more liable to hæmorrhage than the lining membrane of the nose. The blood-vessels which supply this membrane are branches of the common carotid arteries, and the blood is returned from the membrane by veins which join the external jugular veins. Blood may flow from the nose under very varying circumstances; sometimes when the system is in a state of plethora, and at others when in a state of debility. When it occurs in plethoric persons it is usually preceded by pain in the head, vertigo or drowsiness, frightful dreams, increased heat of one side of the face, injection of the eyes, flashes of light before the eyes, increased beating of the temporal arteries, deafness, &c. These symptoms will be present, more or less intense, according to the general condition of the sufferer. This active form of the hæmorrhage comes on in the course of many diseases, as the inflammatory forms of fever, inflammation of the brain, lungs, &c. Where the bleeding comes on in a state of debility it is called passive, and may make its appearance without any premonitory symptoms. This form comes on in the course of low and malignant fevers, and various diseases which come on in a cachectic state of the body.

Bleeding at the nose, when it occurs alone, most frequently comes on in children. After ten or twelve years of age it is oftener seen in boys than girls. It is frequently hereditary, and whole families exist who are liable on slight causes to bleed at the nose. It may be brought on by whatever increases the flow of blood to, or retards the flow of blood from, the head. Thus, mental excitement, anger, shame, protracted study, stooping, sneezing, deep sighing, hallooing, singing, coughing, tumors on the veins, tight neckcloths, &c., may all be exciting causes of the bleeding. Whatever causes absolute or relative plethora, as too free living, the suppresion of accustomed discharges, whatever interferes with the free circulation of the blood, as tight clothes, whatever determines the blood to the surface of the body, as diminished pressure of the atmosphere, as in ascending mountains, a highly heated atmosphere, &c., will also produce it.

Bleeding at the nose is not in itself a dangerous disease. It may, however, come on in states of the body when the system is already exhausted, and be the forerunner of a fatal result. But in inflammatory diseases, and where the person is plethoric, it is frequently a relief to the system, and is followed by a diminution of painful symptoms. In persons, however, after middle age, and who are inclined to plethora, this symptom should be looked upon as indicative of congestion, which may proceed further, and the warning should be regarded, and a diminution in the indulgences of the table insisted on.

In the treatment of bleeding from the nose, regard must be had to the state, age, &c., of the patient. When it occurs in children, and in the great majority of simple cases, all that is required is to make the patient assume the sitting posture, and hold the head backwards; cold should be applied to the face, and a piece of cold metal placed between the nape of the neck and the clothes. Acid drinks may be given at the same time. When the person is plethoric and has suffered much pain in the head, singing in the ears, &c., previously, it will not be advisable to stop the bleeding until these symptoms are relieved. This may be followed by the exhibition of purgatives; and bleeding from the arm should be had recourse to if the head symptoms continue. When the bleeding follows the stoppage of any natural discharge, this latter should be restored. Cupping on the nape of the neck, or even dry cupping, may be recommended in these cases. But in the passive states of the system it is frequently desirable to avert the bleeding without loss of time. Under these circumstances astringents should be applied immediately to the pituitary membrane. A solution of the acetate of lead, of the sulphate of zinc, of iron, of copper, or of alum, may be injected up the nostrils, or a dossil of lint wetted with the solution thrust up the nostril. Tannin or tannic acid may be employed in the same manner. These astringents may also be administered internally with small doses of opium. One of the most effectual means of arresting hæmorrhage from the nose when other means fail is plugging the posterior nares, which may be done by introducing a piece of sponge or lint upon a ligature into the mouth, and carrying it through the nares to the nostril in front. This generally exercises sufficient pressure to arrest the bleeding.

(Copland, *Dictionary of Medicine; Cyclopædia of Practical Medicine*, article Epistaxis.)

EPISTYLE, the first layer of stone placed on columns to form the architrave. The term is derived from the Greek epistylium (ἐπιστύλιον), and that from the words *epi* (ἐπὶ) 'upon' and *stylus*, (στῦλος), 'a column.'

EPITAPH (ἐπιτάφιον, *epitáphium*), an inscription on a tomb; from ἐπὶ, upon and τάφος, a sepulchre. Inscriptions in honour of the dead are perhaps as old as tombs themselves; the most ancient however with which we are now acquainted are probably those of Simonides upon Megistias the soothsayer of the little army of Leonidas, and on the heroes who fell at Thermopylæ, preserved by Herodotus (vii. 228.) Another epitaph of very high antiquity may be referred to in the ancient Greek inscriptions found in the Ceramicus at Athens, upon the warriors who fell at Potidæa 432 years B.C. The original, in a mutilated state, is among the Elgin marbles in the British Museum. (No. 348.) The reader will find other examples of Greek and Roman epitaphs in the Elgin and Townley marbles of the British Museum, published under the superintendence of the Society for the Diffusion of Useful Knowledge.

The earliest epitaphs of this country were those of the Romans or Romanized Britons, which usually began with D. M. (*Diis Manibus*), followed by the name, office, and age of the deceased, and a conclusion which informed the reader by whom or through what means the inscription was erected. This seems to have been the ordinary formula of the sepulchral inscriptions of that period.

Whether the Saxons or the Danes used monumental inscriptions among us, either in their own or in the Latin tongue, has been doubted. The few which we have for people of the Saxon times are the compositions of a later date. Three or four small slabs, however, bearing crosses and some female names, supposed to be those of nuns, were dug up at Hartlepool.

The regular series of English epitaphs begins in the 11th century, when they were still written in the Latin language. One of the most remarkable of this period is that preserved in Sir William Dugdale's Baronage, for William de Warren, earl of Surrey, who died in 1089, copied from the abbey register of St. Pancras, Lewes, of which he was the founder, where it is said to have been engraven on white marble.

Hic Gulielme Comes locus est laudis tibi fomes
Hujus fundator, & largus sedis amator.
Iste tuum funus decorat, placuit quia munus
Pauperibus Christi, quod prompta mente dedisti.
Ille tuos cineres servat Pancratius hæres,
Sanctorum castris qui te sociabit in astris.
Optime Pancratie, fer opem te glorificanti;
Daque poli sedem, talem tibi qui dedit sedem.

A mutilated epitaph for Gundreda, daughter of William the Conqueror, and wife of this earl of Surrey, is still remaining in the church of Southover near Lewes; she died in child-bed in 1085. The generality, however, of the epitaphs of this period are neither so long nor so laboured as the earl of Surrey's. Vitalis, the twenty-first abbot of Westminster, who died in 1082, had only these lines—

A vita nomen qui traxit, morte vocante,
Abbas Vitalis transiit, hicque jacet.

In the 12th century our epitaphs are few. The tomb usually consisted of a single figure; and the inscription added to it was little more than a mere designation of the person: such as that at Hereford, of the year 1148,

Dominus Robertus de Retum episcopus Herefordensis;

or that in the chapter-house at Gloucester, 1176,

Hic jacet Ricardus Strongbow, filius Gilberti Comitis de Pembroke.

Early in the 13th century we begin to find the epitaph in French, occasionally accompanied by promises of absolution to such of those who passed the tomb as might pray for the soul of the deceased. Weever gives an instance of this in his 'Funeral Monuments,' in an inscription for Robert the third earl of Oxford, who died in 1221:—

Sire Robert de Veer le premier Count de
Oxenford le tierz git icy. Dieu de l'ame si lui
Plest face merci. Ki pur l'alme priera XL
Jors de pardon avera. + Pater noster, &c.

At the church of Kingswear, in Devonshire, we have an epitaph of this kind in rhyme:—

Vos qui ici venez
Pur l'alme Philip priez.
Trente jours de pardon
Serra vostre gwerdon.

Henry III.'s epitaph, in the same language, with a prayer for mercy to him, still remains embossed in old capitals round the ledge of his tomb in Westminster Abbey, 1272.

The epitaph in French continued till the middle of the 14th century, after which time inscriptions in the vernacular tongue became common. One of the earliest, perhaps, was that upon a stone over one of the Savile family at Thornhill, in Yorkshire:—

Bonys emongq stonge lys ful
steyl, gwylste the sawle wan-
deris were that God wylethe.

Blomfield, in his 'History of Norfolk,' has preserved a curious specimen of the English of the time, in an epitaph from Holm Church in that county, about 1404:—

Henry Notingham and his wyff lyn here
That mayden this church, stepull, and quere,
Two vestments and bellez they made also,
Christ them save therefore fro wo!
And to bringe ther soules to bles of heven
Saith Pater and Ave with mylde steven.

Gough, in his 'Sepulchral Monuments,' whence much of our information has been obtained, gives the following from the church of St. Peter at St. Albans, 1420:—

In the yere of Christ on thousand and four hundryd ful trew with four and
sixteene
I Richard Skipwith gentylman in birth late fellow of New Inne,
In my age twenti on my sowl partyd from the body in August the 16th day
And now I ly her abyding God's mercy under this ston in clay,
Desyring yow that this sal see unto the Meyden pray for mee
That bare both God and Man,
Like as ye wold that other for ye shold
When ye ne may nor can.

The clergy and religious, however, still preferred Latin, perhaps, as their more familiar idiom; and one or two instances occur, even so late as the middle of the 15th century, where the epitaph is given in Latin rhyme. The last edition of Hutchins's 'Dorsetshire' mentions the following as engraved round the arch of the church door at Durweston, near Blandford, 1459:—

Hic jacet sub tumulo Downton Willielmus humatus;
Rector erat villæ Durweston: Okfordie natus.

The generality of the Latin epitaphs of this period were on strips of brass, and began most frequently with *orate pro anima*, perhaps followed by *miserrimi peccatoris;* an address, says Dr. Johnson, to the last degree striking and solemn, as it flowed naturally from the religion then believed, and awakened in the reader sentiments of benevolence for the deceased, and of concern for his own happiness. There was nothing trifling or ludicrous, nothing that did not tend to the propagation of piety and the increase of devotion.

With the reformation of religion this ceased. The reign of Elizabeth affords but few instances to the contrary; though it is singular that two occur beginning "pray for the soul," upon monuments at Stanton Harcourt, in Oxfordshire, one dated 1566, the other 1569.

After this period the diffusion of learning gave a classic turn even to the epitaph; and though the reigns of Elizabeth and James I. can furnish but few of a pure standard, there is one of Ben Jonson's on the Countess of Pembroke which scarcely yields to any in the Anthologia:—

Underneath this sable hearse
Lies the subject of all verse:
Sidney's sister, Pembroke's mother.
Death, ere thou canst find another,
Good, and fair, and wise as she,
Time shall throw a dart at thee.

The epitaph on Sir Christopher Wren need hardly be repeated, though it is said to have been borrowed. In real merit it is probably surpassed by the latter part of that in King's College Chapel, Cambridge, over the resting-place of Thomas Crouch:—

Aperiet Deus tumulos; et educet
Nos de sepulchris.
Qualis eram, dies isthæc cum
Venerit, scies.

Wit and humour have also marked the composition of the epitaph in almost all ages. Innumerable instances will be found in all the printed collections. Margaret of Austria composed for herself the following couplet, when in imminent danger of shipwreck:—

Cy gist Margôt, noble demoiselle,
Deux fois mariée, et morte pucelle.

Collections of epitaphs, ancient and modern, are numerous; there are many of great merit in the Greek Anthologia. A very large collection of epitaphs will be found in 'Theatrum Funebre, exhibens per varias scenas Epitaphia nova, antiqua, seria, jocosa, &c., in quatuor partes distinctum, extructum a Dodone Richea (seu Ottone Aicher),' 4to, Salisburgi, 1675; Hacket's 'Select and Remarkable Epitaphs on Illustrious and other Persons,' 2 vols. 8vo, 1757: and Le Neve's 'Monumenta Anglicana,' probably preserve the best English collections. Many curious and interesting epitaphs will be found in the volumes of 'Notes and Queries' for 1858, and preceding years. The Society of Antiquaries in June, 1858, invited the contribution from all quarters of authentic copies of monumental inscriptions, with a view to their preservation, and probably publication.

The funeral orations of the Greeks were called by the name of *Lógos Epitáphios* (Λόγος Ἐπιτάφιος), or a discourse over the tomb made at the time of interment. It is only necessary to mention this to prevent any confusion of this kind of epitaph with that which is the subject of the present article.

EPITHALA'MIUM (*ἐπιθαλάμιον*, from *ἐπὶ*, "at" or "near," and *θάλαμος*, "chamber," especially that of a new-married couple), a poem composed in honour of a marriage. It was sung by youths and maidens conjointly, at the door of the bridal chamber, after the bride and bridegroom had entered, and also before they rose in the morning. The first Greek epithalamium known to have been written was a poem by Hesiod, now lost, on the marriage of Thetis and Peleus. The most remarkable extant are those of Catullus, who has left three beautiful specimens of this sort of composition. The first, on the marriage of Julia and Torquatus, is the most curious and interesting as an illustration of manners. That on the marriage of Peleus and Thetis, which is probably only a fragment, is one of the most beautiful extant specimens of Latin poetry. Among the Hebrews, as well as the Greeks and Romans, this species of rejoicing was in use. The subject is hardly in accordance with modern manners. Spenser has treated it beautifully and delicately in his Prothalamium and Epithalamium on the marriage of the Ladies Somerset. Many other English specimens may be found, especially among the writers of the 17th century: but we know of none remarkable enough to require notice.

EPOCH. (Astronomy.) This term is frequently applied to signify, not a moment of time, but the longitude which a planet has at that moment of time. In order to predict the longitude of a planet at any epoch, some preceding epoch must be taken, at which the longitude is known. This latter is called, *par excellence*, the epoch; and the term longitude at the epoch has been abbreviated into epoch.

EPOCH, in chronology. [ÆRA.]

EPODE (in Greek *ἐπῳδὸς*, *after-song*, from *ἐπὶ*, "on" or "upon," and *ᾠδή*, "song") is one of the three divisions of the Greek ode. [CHORUS.] The performers in singing it stood still; it was not, like the strophe and antistrophe, symmetrical with another member of the ode; so that the poem was unfettered as to its length and as to the choice of measures. The epode, however, is not essential to an ode; many of the Greek choruses have none. Most of Pindar's odes, on the contrary, have an epode interposed between each antistrophe and the following strophe. Epode, according to the grammarians, is also a metrical term given to those measures in which a short verse follows a long one, of which the former is called *proodic*, the latter *epodic*. Hence the fifth book of Horace's Odes is called the Book of Epodes, because nearly all of them are written in that sort of measure: as, for instance,—

"Ibis Liburnis inter alta navium,
Amice, propugnacula."

EPROUVETTE is an apparatus for determining the strength of gunpowder. Eprouvettes are of two kinds: the gun eprouvette, which gives the strength by the length of recoil; and the mortar eprouvette, which gives it by the distance an accurately turned heavy ball is thrown by a small charge of powder. Mr. Robins ('New Principles of Gunnery') first proposed the employment of such a machine; but Dr. Hutton, of Woolwich, afterwards considerably improved its construction.

The gun is fixed near its centre of gravity to the lower extremity of an iron rod, which may be about 7 feet 6 inches long, and its base is attached by a short brace to an arm which projects from the rod, an adjusting screw being provided for the purpose of keeping the axis of the bore perpendicular to the same rod. Sometimes, however, a frame of iron, like the letter A, serves to suspend the gun, which is then fixed at two places in collars at the lower extremities of the frame. To the upper part of the rod or frame is attached a horizontal axle of steel, about which the gun is to vibrate; and each extremity of this axle rests in a socket at or near the top of the frame which constitutes the stand or support of the gun and its suspending apparatus.

From the lower side of the gun projects downwards a rod or style of iron, which is pointed at its lower extremity, the point being in a line drawn from the middle of the horizontal axis of suspension through the centre of gravity of the gun. Under the latter, and resting on the ground, is a block of wood, in the under surface of which is cut a groove, in a vertical plane, in the form of a portion of a circle whose centre is at the middle of the axis of suspension; and this groove being filled with soft wax, the point of the rod projecting below the gun, in the recoil of the latter, scratches on the wax a circular arc: the measure of this arc gives, of course, the angle of the recoil.

Instead of this pointed rod and grooved block, a quadrant of brass of any convenient radius, as 12 inches, is sometimes fixed in a vertical position to the rod or frame which carries the gun, the horizontal axis of suspension passing through its centre; the quadrant, whose arc is graduated, vibrates with the gun, and an index at the extremity of a bar on that axis remains at rest till the gun has recoiled as far as the force of the fired gunpowder can impel it; when, by a simple contrivance, it is made to return with the quadrant, showing, by the degree in coincidence with it, the extent of the recoil.

In the eprouvette constructed by Dr. Hutton, the quadrant had on it three graduated arcs: one of these showed the degrees in the angle of recoil; another showed by inspection the length of the chord; and the third showed in like manner the length of the versed sine of the arc of recoil.

In using the instrument, the gun is charged with a given quantity of powder, which is introduced without a cartridge, and is fired, when exactly in a horizontal position, by means of a piece of quick match: the extent of the arc of recoil is then to be measured or read.

The velocity acquired by a body on describing half a vibration in a circular arc, varies (by mechanics) with the square root of the vertical height, or with the chord of the half vibration: hence, if by the explosions of equal charges of different kinds of powder in a suspended gun, the latter be made to recoil from a vertical position through arcs or angles which are measured in degrees, the velocity resulting from the force which produced the recoil being equal to that which the gun would have acquired in descending by gravity from the upper extremity to the lowest point of the arc; it follows that the chords of those arcs or angles will express the relative velocities produced by the different kinds of powder. Again, by mechanics, the forces are as the squares of the velocities; and these, when produced by a body descending on circular arcs, are as the versed sines of the arcs; therefore the angles of recoil, or the half vibrations, being found from the experiments, their versed sines will express the relative forces of the different kinds of powder.

A gun suspended in the manner above described has been employed, instead of the ballistic pendulum, to determine, by its recoil, the initial velocity of the shot fired from it with a given charge of powder. [BALLISTIC PENDULUM.]

The mortar eprouvette generally consists of an eight-inch Gomar mortar, fired with a very small charge (2 to 4 ozs.) and an accurately turned iron shot. The range required for 4 ozs. of powder is about 380 feet. This method is the one usually adopted for testing powder, and is employed for testing the powder made for government by contractors. Its comparative results for different powders, unless the powders are of the same size grain, are, however, wholly fallacious. A small charge of powder *fine grained* will give a much greater range than the same charge of the same powder *coarse grained*. When, however, the charges are large, the coarse-grained powder gives the greatest range; the interstices between the grains being large, allow the heated gas to find its way through and inflame the whole charge more rapidly, which is more than compensated for when the charge is small by the greater extent of surface exposed by the small grains. [Gunpowder.]

EPSOM SALT. [Magnesium, *Sulphate of*.]

EQUAL. Two magnitudes are equal when one of them may be made to coincide with the other. This is the geometrical definition of Euclid, and is placed by him among the axioms, though in reality it is nothing more than the definition of the word equal. Nor is it quite sufficient: a triangle, for instance, and a parallelogram, may be equal in area, and yet neither can, without alteration of form, be made to occupy the same space as the other. The truth is, that the idea of equality is one which will admit no definition; and moreover, it is to the more general notion of the existence of ratio (of which equality is one particular case) that all discussion upon this term should be referred. Nor is the notion of equality to be confined to magnitudes connected with space.

Some geometers have proposed to use the word equivalent as applied to surfaces of equal area but different forms; and the distinction is at least harmless. We cannot say more; for when it is once established that the term used by Euclid is to be understood in a wider sense than the words of the axiom will bear, no liability to confusion remains.

There is one little warning which beginners in mathematics often want. *Equal* is an adjective which, by its own meaning, has no singular number except in conjunction with *to*. Thus A and B may be *equal;* and A may be *equal to* 8; but there is no meaning in "A is equal," taken alone.

EQUALITY, APPROACH TO. As a general rule, that which may be stated as absolutely true when an equation is true, may be stated as nearly true when that equation is only nearly true. Usage of words however is apt to lead to mistake when it is equality, and nearness to equality, which are in question: A and B are absolutely equal when either of the following equations is true; one of them being of course a consequence of the other:

$$\mathrm{A}-\mathrm{B}=0 \qquad \frac{\mathrm{A}}{\mathrm{B}}=1$$

and it is usual to say that a *small* quantity is *nearly nothing* or *near to nothing*. In strictness, we might as well say that a large quantity is near to infinity, as that a small quantity is near to nothing: both infinity and nothing are limiting terms, except only as to the latter, when obtained by subtraction. [Infinite.] Nevertheless we can hardly hope to abolish the common idea of small quantities being next to nothing: we must therefore guard those who accept this phraseology from the mistake to which it very frequently leads.

It is not true that quantities are necessarily nearly equal when their difference is near to nothing (meaning small). If by small we here understand small with respect to the quantities themselves, it is true; but not otherwise. If A—B be a small fraction of A, let it be m A, where m is a small fraction of unity; then A—B$=m$ A gives

$$\frac{\mathrm{B}}{\mathrm{A}}=1-m$$

or B and A are in the ratio of $1-m$ to 1, nearly that of 1 to 1. But if A and B be both small, their difference is small: and yet that difference may be itself many times greater than the smaller of the two quantities from which it was obtained. If the bulk of the sun be unity, the earth and moon are both small fractions; but not nearly equal. When therefore we want to think of approach to equality, we must rely on approach to

$$\frac{\mathrm{A}}{\mathrm{B}}=1,\text{ not to }\mathrm{A}-\mathrm{B}=0$$

We are here merely guarding a phrase, not explaining principles at length. In the articles Infinite; Limit; Fractions, Vanishing, will be found the elementary notions, proper attention to which will secure the beginner from error.

When a person, for any common purpose, speaks of a small quantity as next to nothing, he compares it with the whole mass from which it is taken, and he always means by small that which is a small fraction of any important quantity. The terms small and great being purely relative, may have many meanings in different circumstances; but with that we have here nothing to do. Whatever *small* may mean, we have no right to say that quantities of small difference are nearly equal, except only when the relative word small may be properly used in relation to the quantities themselves.

This last caution is the more necessary to the young mathematician, from his frequently meeting with the words small and great in an absolute sense. Though this absolute use of the words is only an abbreviation [Infinite,], he may, without care, now and then forget that it is so.

EQUATION (Astronomy). The characteristic of all the heavenly motions is, that they nearly follow a simple law, but not quite. The small corrections which must be added to or subtracted from the results of the simple law, in order to secure accurate prediction, are called equations. Thus, the moon moves round the earth with a motion which is not very far from uniform; the average motion is therefore ascertained, and, starting from a given epoch, at which the true place is known, the longitude for that epoch is first increased by the longitude which would have been described by the moon, had she moved with her average motion. The result must then be altered by a number of different *equations*, some being consequences of the elliptic figure of the moon's orbit, some of the sun's attraction, &c. When all these equations have been annexed, the result is the moon's longitude for the time proposed.

EQUATION (in pure mathematics), an assertion of the equality of two magnitudes, represented to the eye by the symbol=. Thus A=B is to be understood as a proposition, declaration, or assertion that the magnitude A is equal to the magnitude B. It is not immaterial to insist upon this definition; for beginners frequently confound the notion of an equation (an *assertion* of equality) with the idea of equality itself, and speak of two *equations* being *equal*, and of one equation being greater than another.

To treat of equations is to write on mathematics in general; for when two magnitudes A and B are of the same kind, A must be either greater than, equal to, or less than B. The objects of mathematics generally require that it should be determined (supposing A and B not equal) by how much one exceeds the other: and the assertion that A exceeds B, and exceeds it by M, is equivalent to the *equation* A=B+M. The assertion of inequality is called by continental writers an *inequation*: and one work (we are not aware of any other) has been written on the subject; Canard's 'Traité des Inéquations,' &c.

An equation may be one of two kinds: necessarily true, whatever may be the value of the symbols employed, and called *identical;* or true only upon the supposition of some particular value being given to certain magnitudes, or of some particular relations existing. The latter species are called equations of *condition*. Thus—

$$a=a, \quad a+a=2a, \quad (a+b)^2=a^2+2ab+b^2$$

are identical equations: while

$$2a+1=13, \quad x^2=5x-4$$

are equations of condition; the first requiring that a should be 6, and the second that x should be either 4 or 1. Again, $a+b=1$ is an equation of condition.

Certain equations being supposed to be true, the determination of all their consequences, that is, of all equations which follow from them, is the great object of mathematical analysis. The difficulties which lie in the way are of various classes, and give rise to various modes of considering equations. These are so widely separated from each other, and diverge into such different subjects, that we can here do no more than point out two or three of the most remarkable species of inquiries. This we shall do in articles headed by the word Equation.

The theory of equations is a branch of algebra which is not correctly named; and which we refer to Theory of Equations. It is the theory of *rational and integral expressions*, which, having grown out of attempts to solve equations, and having the solution of equations among its most important requirements, has gained a name which does not express its full scope.

EQUATION ANNUAL. [Moon.]

EQUATION OF THE CENTRE. [Moon; Sun, &c.]

EQUATION OF THE EQUINOXES. [Precession.]

EQUATION OF TIME. [Sun.]

EQUATION, BINOMIAL. A binomial equation is an algebraical equation of two terms. Its form is therefore $ax^n+bx^m=0$, all the consideration of which may easily be reduced to that of one or other of the forms $x^n \pm a^n=0$ (n being integer). All that is necessary will be given in the article Root, and we shall here confine ourselves to such statement of the mode of resolving $x^n \pm a^n$ into factors as may be useful for reference.

First, as to x^n-a^n. Of this $x-a$ is always a factor, and if n be even, $x+a$ is also a factor. The remaining factors are all of the form

$$x^2-2\cos\theta.\ ax+a^2$$

in which θ may be either the quantity $\frac{2\pi}{n}$ or any multiple of it less than $\frac{1}{2}n$. Thus whether n be 10 or 9, we go as far as four times $2\pi \div n$, since 4 is the integer next less than the half either of 10 or 9. According, if $\frac{2\pi}{n}=\nu$, and if k be the integer next less than the half of n, we have

$$\begin{aligned} x^n-a^n = {} & (x-a) \\ & \times (x+a,\text{ if } n \text{ be even}) \\ & \times (x^2-2\cos\nu.\ ax+a^2) \\ & \times (x^2-2\cos 2\nu.\ ax+a^2) \\ & \times \quad . \quad . \quad . \quad . \quad . \quad . \quad . \\ \text{up to } & \times (x^2-2\cos k\nu.\ ax+a^1). \end{aligned}$$

Next, as to x^n+a^n. Of this $x+a$ is a factor if n be odd: and the remaining factors are of the above form, θ being $\frac{\pi}{n}$ or any *odd* multiple of it which does not equal n. Thus whether n be 10 or 11, we go as far as 9 times $\pi \div n$, since 9 is the last odd integer which does not equal either 10 or 11. If then $\nu = \pi \div n$, and k be the last odd number which does not equal n, we have

$$\begin{aligned} x^n + a^n = {} & (x + a, \text{ if } n \text{ be odd}) \\ & \times (x^2 - 2a \cos \nu .\ ax + a^2) \\ & \times (x^2 - 2a \cos 3\nu .\ ax + a^2) \\ & \times (x^2 - 2a \cos 5\nu .\ ax + a^2) \\ & \times \ . \quad . \quad . \quad . \quad . \quad . \quad . \\ \text{up to } & + (x^2 - 2a \cos k\nu .\ ax + a^2). \end{aligned}$$

Closely connected with the binomial equation is the trinomial equation—

$$x^{2n} \pm 2 \cos \lambda .\ a^n x^n + a^{2n} = 0$$

the left-hand side of which is thus reduced :—

For $x^{2n} - 2 \cos \lambda .\ a^n x^n + a^{2n}$ the factors are—

$$x^2 - 2 \cos \frac{\lambda}{n} .\ ax + a^2$$

$$x^2 - 2 \cos \frac{\lambda + 2\pi}{n} .\ ax + a^2$$

$$x^2 - 2 \cos \frac{\lambda + 4\pi}{n} .\ ax + a^2$$

and so on up to

$$x^2 - 2 \cos \frac{\lambda + \overline{2n - 2}\pi}{n} .\ ax + a^2$$

For $x^{2n} + 2 \cos \lambda .\ a^n x^n + a^{2n}$ the factors are—

$$x^2 - 2 \cos \frac{\lambda + \pi}{n} .\ ax + a^2$$

$$x^2 - 2 \cos \frac{\lambda + 3\pi}{n} .\ ax + a^2$$

$$x^2 - 2 \cos \frac{\lambda + 5\pi}{n} .\ ax + a^2$$

add so on up to

$$x^2 - 2 \cos \frac{\lambda + \overline{2n - 1}\pi}{n} .\ ax + a^2$$

(For the *algebraical* solution of binomial equations, see the works of Gauss or Legendre on the theory of numbers, or Murphy's *Theory of Equations* in the *Library of Useful Knowledge.*)

EQUATION OF PAYMENTS, an arithmetical rule, for the purpose of ascertaining at what time it is equitable that a person should make payment of a whole debt which is due in different parts payable at different times. This rule is now of no practical use, as it rarely, if ever, happens that it is considered necessary to *equate* payments. Sums of money due at future periods are generally secured by bills of exchange or by promissory notes, and when the date of payment is altered, it is usually immediate payment which is contemplated. [DISCOUNT.]

EQUATION, PERSONAL. It is a fact which has now been for some years established, and which might reasonably have been suspected, that different persons, attempting to observe the precise moment of a phenomenon, by means of a clock which beats seconds, do not agree exactly in their results, but differ generally in one and the same way, one of the observers being almost always a little before the other in the moment which he assigns to the phenomenon. If this had not been the case, if one of the observers had been about as often before the other as behind him, the difference could only have been considered a simple casualty. But, looking upon the constant occurrence of a difference of one kind between two observers, it becomes obvious that the cause is in the organs of the men themselves; and that physical constitution, temperament, habit, &c., make differences between one person and another.

Personal Equation is a name given to the quantity of time by which a person is in the habit of noting a phenomenon wrongly; and it may be called *positive* or *negative*, according as he notes it after or before it really takes place. Thus if A and B are severally in the habit of noting events 3-tenths of a second after and 4-tenths of a second before they take place, their personal equations may be described as being $+ 0^s{\cdot}3$ and $0^s{\cdot}4$.

The absolute personal equation of any one is a thing undiscoverable; since we can only refer one human observer to another, and note the difference of their times of observing the same phenomenon. If we could cause a thousand persons to note a given definite phenomenon by one clock, and if we could take the mean of all their results, we might say that there is very strong reason to presume that the mean is the time which perfect organs would have noted: for we may think that the chances are much in favour of human imperfection being, in the mass, as much of one kind as of the opposite. But a little consideration will show that this reasoning is not to be relied on. It may be that the whole race has, by its constitution, a rather large personal equation of one or the other kind: for we can only see the differences, without knowing upon what quantities they are differences. This question is, however, practically immaterial; for any given amount of personal equation common to the whole race is equivalent to making all the clocks wrong by the same quantity. Suppose, for example, that every person suddenly received an addition of one second to his personal equation, or began to note phenomena a second later. The astronomers would then begin to find the clocks a second too fast, in comparing observation with prediction; as soon as the clocks had been rectified every thing would be as before.

The first notice we have of personal equation is in an announcement by Maskelyne, in the volume of Greenwich Observations for 1795. He tells us that he was obliged to part with one of his assistants, because the latter, who had till then always agreed with him in his observations, suddenly began, in August, 1794, to observe half a second later: and that in January, 1796, the difference amounted to 8-tenths of a second. Maskelyne inferred that his assistant had contracted some bad habit of observation: it is now very well known that age causes persons to observe later than they did before, though it is not usual for the habit to undergo such sudden changes as in the above case. In 1823 Mr. Bessel, at Königsberg, ascertained that he was in the habit of observing phenomena as much as $1^s.22$ before his assistant Mr. Argelander. The latter left his post to take charge of the observatory at Bonn: but, passing through Königsberg in 1832, Mr. Bessel took the opportunity to make some further comparisons with him; and it was found that the above quantity was reduced to $1^s{\cdot}06$. Age had brought them nearer together. A close trial of the subject was made by MM. Quetelet and Sheepshanks, 1838-1841, in determining the longitude of Brussels by transmission of chronometers between that place and Greenwich. This method of course requires the most careful transit observations at both places, and the personal equation* becomes of considerable importance. It was necessary that some observer should compare himself with M. Quetelet at Brussels, and with the assistants at Greenwich. This was undertaken by Mr. Sheepshanks, and the result ascertained was, that he came, one observation with another, 45-hundredths of a second behind M. Quetelet, and 27, 35, and 24-hundredths before MM. Main, Henry, and Ellis, severally. The result was that the longitude of Brussels was found to be three-quarters of a second less than it would have been supposed to be if the difference of personal equations had been unknown. (See a memoir on the difference of the longitudes of Brussels and Greenwich, by MM. Quetelet and Sheepshanks, *Mém. de l'Acad. Roy. de Bruxelles*, vol. xvi.)

EQUATIONS, DIFFERENTIAL, and EQUATIONS of DIFFERENCES. The difficulty in this case is the inversion of the processes of the Differential Calculus and the Calculus of Differences. We give an example of each case :—$\dfrac{d^2y}{dx^2} - \dfrac{dy}{dx} = x$, is a differential equation. The question asked is, what is y, that function of x, of which it is the property that the first differential coefficient subtracted from the second will always leave x.

$\Delta y = y + 1$, is an equation of differences. The question asked is, what must y (understood to be a function of x) be, in order that an increase of a unit in the value of x shall increase y by $y + 1$. This is in reality a simple functional equation, as follows. Required ϕx so that

$$\phi\,(x+1) - \phi\,(x) = \phi\,x + 1.$$

The two classes of equations, thus briefly noticed, include in their history that of most of the mathematico-physical sciences. The progress of the theory of gravitation since Newton is contained in successive attempts to solve certain differential equations. All questions of dynamics, electricity, the theory of light and heat, &c. &c., resolve themselves at last into the solution of differential equations. Works on the differential calculus contain but little on this subject, its utility considered; and it is to the applications themselves that the student must look for further information.

We shall now give a slight synopsis of results, such as may be useful to the advanced student, as a guide to his reading, or for reference. We have not room either to teach the subject or to illustrate it by examples. We may refer to the following works:—Moigno, 'Leçons de Calcul Differentiel,' &c., vol. ii. Paris, 1844, 8vo.; De Morgan, 'Differential and Integral Calculus,' London, 1842, 8vo. (Lib. of Useful Knowledge); various numbers of the 'Cambridge Mathematical Journal,' Cambridge, 1839, &c. 8vo.; Brooke, 'Synopsis of the . . Formulæ . . of Pure Mathematics,' Cambridge, 1829, 8vo.; Peacock, Herschel, and Babbage, 'Collection of Examples,' &c., Cambridge, 1820, 8vo.; Gregory, 'Examples of the Differential Calculus,' Cambridge, 1841, 8vo.; Boole, on 'Differential Equations,' Cambridge, 1859. We must confine ourselves to a selection from striking points, or our article would exceed all reasonable limits.

1. Let there be a function $\phi\,(x, y, a, b, c \ldots)$, or ϕ, containing the variables x and y and the n constants, $a, b, c, \ldots$ If we make $\phi = 0$, we tacitly require that y should be a function of x. If between $\phi\,(x, y \ldots) = 0$, and the result of complete differentiation, $\phi'\,(x.\ y, \ldots) = 0$, we eliminate one of the constants, we get a new equation contain-

---

* It is usual to call the difference between two observers the *personal equation*; but this ought to be called the *difference of their personal equations*, or their *personal difference*. The personal equation of an observer is, properly speaking, the difference between him and the average of the human race.

ing x, y, y' (or $dy : dx$) and all the rest of the constants; and according as we eliminate one or another constant, we have one or another of as many such equations as there were constants. These are called differential equations of $\phi = 0$, and they are said to be of the *first order.*

2. The word *order* refers to the number of differentiations, the word *degree* to the highest power of the highest differential coefficient which enters. Thus $y''^4 + y'^5 = x$ is a differential equation of the second order and the fourth degree. Let the accents always denote complete differentiation with respect to x. For partial differentiation we shall save room by writing as follows :—ϕ'_x for $\frac{d\phi}{dx}$, ϕ'_y for $\frac{d\phi}{dy}$, &c.

3. If we eliminate two of the constants between $\phi = 0, \phi' = 0, \phi'' = 0$, we have a differential equation of the second order, and so on; there are altogether $\frac{1}{2} n (n-1)$ differential equations of the second order, if we have n constants. And generally, when there are n constants, there are as many differential equations of the mth degree as there are ways of taking m out of n things. Thus there is only one equation of the nth degree.

4. If there be a system of p equations between $p + 1$ variables, so that p of the variables are functions of the remaining one, and if we differentiate each equation once, we can eliminate p constants, and form p equations of the first order. With p second differentiations, we can eliminate p other constants, and so on. And if there were $p + q$ variables, we should have similar systems with q independent variables.

5. Equations of differences are formed in a corresponding way by taking differences instead of differential coefficients. Thus suppose u_x means u, a function of x, and $\phi\ (x, u_x, a) = 0$. Change x into $x + \Delta x$, usually into $x + 1$, and let u_x then become u_{x+1}, or $u_x + \Delta u_x$. If we eliminate a between $\phi\ (x, u_x, a) = 0$ and $\phi\ (x+1, u_{x+1}, a) = 0$, we have an equation of the form $\psi\ (x, u_x, u_{x+1}) = 0$, or $\psi(x, u_x, \Delta u_x) = 0$, as we please, and this is an equation of differences of the first order. But exactly the same equation would be obtained, if for a we had substituted any function of $\cos\ (2\pi x)$, or of $\cos\ (2\pi x \div \Delta x)$. On this point see INVARIABLE.

6. When there are more than two variables, say three, it is possible to form an equation in which an arbitrary function of a definite function of two of them shall be eliminated. Thus, if $\phi \left\{x, y, z, \psi\alpha\ (x, y)\right\} = 0$, in which z is an implied function of x and y and $\alpha\ (x, y)$ a given function; we differentiate with respect to x and y separately, and produce three equations involving $x, y, z, z'_x, z'_y, \psi\alpha\ (x, y)$ and $\psi'\alpha\ (x, y)$. From these three eliminate the two last, ψ and ψ', and we get an equation involving only x, y, z, z'_x, z'_y, in definite forms. This is called a partial differential equation.

7. The analogies between the constants of a common differential equation and the arbitrary functions of a partial one must not be relied on as capable of being carried all lengths. It is not, for instance, universally true that two arbitrary functions may be completely eliminated by differentiations of the second order.

We now consider common differential equations of the first order.

8. Let $y = \phi\ (x, c)$, and $y' = \phi\ (x, c)$, and let elimination give $y' = \chi(x, y)$, the differential equation. There is another mode of arriving at the same result. Let $y = \phi\ (x, c)$ give $c = \Phi\ (x, y)$, or $0 = \Phi'_x + \Phi'_y\ .\ y'$. The constant here disappears by mere differentiation, and $\chi\ (x, y)$ must be identical with $-\Phi'_x : \Phi'_y$.

9. The difficulty of returning to the primitive from the equation $y' = \chi\ (x, y)$ consists in that of reducing it to the form $\Phi'_x + \Phi'_y\ .\ y' = 0$. Generally speaking, common factors are made to disappear, and the restoration of these factors is a problem of exactly the same difficulty as the solution of the equation.

10. The quantity $\mathrm{P} + \mathrm{Q}y'$, P and Q being functions of x and y, is integrable at once when $\mathrm{P}'_y = \mathrm{Q}'_x$. When this condition, which is usually called the criterion of integrability, is satisfied, the integral is

$$\int \mathrm{P}dx + \int \left(\mathrm{Q} - \frac{d}{dy} \int \mathrm{P}dx\right) dy$$

in which y is constant in the first integration, and x in the second. Any arbitrary constant may be added. Either of the following forms are also integrals of $\psi\ (x, y) + \chi\ (x, y)\ .\ y'$, if the criterion be satisfied.

$$\int_a^x \psi\ (x, y)\ dx + \int_b^y \chi\ (a, y)\ dy$$

$$\int_b^y \chi\ (x, y)\ dy + \int_a^x \psi\ (x, b)\ dx.$$

11. The equation $y' = \chi\ (x, y)$ can have no other primitive with an arbitrary constant, except $y = \phi\ (x, c)$ from which it was derived. But it may have another solution which has not an arbitrary constant, or even more than one: these are called singular solutions. A singular solution makes χ'_x and χ'_y infinite if y be substituted from it in terms of x. It also makes Φ'_x and Φ'_y infinite in the same manner. All the solutions of either or both $\phi'_x = 0$ and $\Phi'_y = 0$ are singular solutions; and all the singular solutions are thus found. But though the most prominent and useful singular solutions are sure to be obtained from $\chi'_x = \infty$ and $\chi'_y = \infty$, these equations may not contain all singular solutions, nor do they give nothing but singular solutions. But any solution of $\chi'_y = \infty$ which makes $\chi'_x + \chi'_y\,\chi$ finite is a singular solution of the equation $y' = \chi$.

12. The singular solution may also be found from the primitive $y = \phi\ (x, c)$, as follows. Eliminate c between $y = \phi\ (x, c)$ and $0 = \phi'_c\ (x, c)$, the result is the singular solution. This rule and the last are subject to exception, when the singular solution takes the form $x =$ constant or $y =$ constant.

13. The geometrical character of a singular solution is as follows. If $y = \phi\ (x, c)$ be the equation of a family of curves, that is, of one curve for each value of c, the differential equation $y' = \chi\ (x, y)$ also belongs to every member of that family. The singular solution is the equation of the curve which touches every one of the family of curves.

14. The equation $y = y'x + \phi\ (y')$ is historically remarkable as having led to the theory of singular solutions: it is called *Clairaut's form.* The complete primitive is $y = cx + \phi c$, belonging to a family of straight lines: the singular solution is found by eliminating c between this and $x + \phi' c = 0$.

15. Singular solutions are either *intraneous,* contained in the general solution as particular cases; or *extraneous,* not so contained. These two species do not differ in geometrical character. A remarkable theorem of Cauchy discriminates between them, as follows :—

Let $y = \mathrm{P}$ be a solution of $y' = \chi(x, y)$, and let β be any small quantity. If, then, x being constant,

$$\int_{\mathrm{P}}^{\mathrm{P}+\beta} \frac{dy}{\chi(x, y) - \chi(x, \mathrm{P})}$$

be finite, $y = \mathrm{P}$ is an extraneous solution; if infinite, intraneous.

16. It is not often that the factor which makes an equation integrable can be recovered in any general form. As soon as the solution is obtained, it can always be found; but the only use of it is to find the solution. There is always an infinite number of such factors, any one of which will do. When in $\mathrm{P} + \mathrm{Q}y'$, the criterion $\mathrm{P}'_y - \mathrm{Q}'_x$ is not $= 0$; yet if $\mathrm{Q}^{-1}(\mathrm{P}'_y - \mathrm{Q}'_x)$ be a function of x only, and not of y, and if $\int \mathrm{Q}^{-1}\ (\mathrm{P}'_y - \mathrm{Q}'_x)\ dx = \mathrm{V}$, then $\epsilon^{\mathrm{V}}\ (\mathrm{P} + \mathrm{Q}y')$ is integrable.

17. The equation $y' + \mathrm{P}y = \mathrm{Q}$, in which P and Q are functions of x only, is always integrable. The factor of integration is $\epsilon^{\int \mathrm{P}dx}$, and the complete integral is

$$y = \epsilon^{-\int \mathrm{P}dx} \int \mathrm{Q}\epsilon^{\int \mathrm{P}dx}\ dx + c\ .\ \epsilon^{-\int \mathrm{P}dx}.$$

The equation $y' = \mathrm{P}y + \mathrm{Q}y^2$ is reduced to the preceding form by making $y = z^{-1}$; and $y' = \mathrm{P}y + \mathrm{Q}y^n$ by making $z = y^{1-n}$.

18. When P and Q are homogeneous functions of x and y, that is, when they are both of the form $x^n\ \phi\ (y : x)$, with the same value of n, the integrating factor is $(\mathrm{P}x + \mathrm{Q}y)^{-1}$. But generally the following method is more convenient. Having

$$\phi\ (x : y) + \psi\ (x : y)\ .\ y' = 0$$

assume $y : x = u$, from whence

$$\frac{dx}{x} = -\frac{\psi u du}{\phi u + u\psi u}$$

to which common integration can be applied. The equation is now reduced to one in which the variables are said to be separated.

19. It is hardly necessary to say that the variables can be immediately separated in $\mathrm{P} + \mathrm{Q}y' = 0$, whenever P and Q are both of the form $\phi x \times \psi y$.

20. It often happens that, when direct processes would require the previous solution of an equation of indefinite form, indirect processes will succeed in reducing the question of solution to one of elimination. Thus $x = f\ (y')$ is solved when y' is eliminated between this and

$$y = y' fy' - \int fy'\ dy' + c,$$

and $y = fy'$ is solved when y' is eliminated between it and

$$x = x' f\left(\frac{1}{x'}\right) - \int f\left(\frac{1}{x'}\right) dx' + c$$

where x' means $1 : y'$.

21. The equation $y = x\ \phi y' + \psi y'$ can be reduced to elimination, thus: Let $y' = z$, then

$$\frac{dx}{dz} - \frac{\phi' z}{z - \phi z} x = \frac{\psi' z}{z - \phi z}$$

which is of the form integrated in § 17. Eliminate z between the result of this and $y = x\phi z + \psi z$.

22. The equation $y = \phi\ (x, y')$ can be reduced to a form of the first degree and elimination. Let $y' = z$, then $z = \mathrm{P} + \mathrm{Q}z'$, where P and Q are $\phi'_x\ (x, z)$ and $\phi'_z\ (x, z)$. If this equation can be integrated, we eliminate z between the result and $y = \phi\ (x, z)$. The form $x = \phi\ (y, y')$ may be treated in a similar manner. Or generally, let the equation be $\phi\ (x, y, y') = 0$; that is, $\phi\ (x, y, z) = 0$, which gives by differentiation a form $\mathrm{P} + \mathrm{Q}z + \mathrm{R}z' = 0$. If from this we eliminate y, by substitution from the preceding, we have an equation of the first degree as to z'; from which, if integration be possible, elimination will determine the relation between x and y.

23. Any differential equation whatever may have a chance of reduc-

tion to an easier form in the following way: Let Y be a function of X, and let Y' mean $dY : dX$, &c. Take the following sets of quantities:—

x	y'
y	$xy'-y$
y'	x
$xy'-y$	y
y''	$1 : y''$
$1 : y''$	y &c.

In $\phi(x, y, y', y'', \&c.)=0$, write for each of x, y, y', &c., the quantity opposite to it in the list above. If the equation thus produced can be integrated into $Y=\psi X$, then by eliminating X from $x=Y'$, $y=XY'-Y$, the relation between x and y which satisfies $\phi(x, y, y', \&c.)=0$ is found.

24. Various substitutions will sometimes aid in the solution of an equation, as $y=ux$, $y=u^{-1}$, $=u^m$, $y=\epsilon^u$, and so on: sometimes, when a couple of expressions of the form $ax+by+c$, $a'x+b'y+c'$, occur, it will be convenient to introduce two new variables derived from equating the preceding to $Au+Bw$ and $A'u+B'w$. We have given the most effective general methods; the number of transformations * which have succeeded in particular cases is very large.

25. When the equation is of the first order, but of a higher degree, as

$$P_n y'^n + P_{n-1} y'^{n-1} + \dots + P_1 y' + P_0 = 0,$$

the theoretical mode of proceeding, occasionally convenient enough in practice, is to find the n values of y', say $y'=\phi_1(x, y)$, $y'=\phi_2(x, y)$, &c. If these can be separately integrated, giving, say $\psi_1(x, y, c)=0$, $\psi_2(x, y, c)=0$, &c., then the complete primitive of the equation is

$$\psi_1(x, y, c) \times \psi_2(x, y, c) \times \dots = 0.$$

26. When, in the last, P_n, P_{n-1}, &c., are all homogeneous functions of x and y of the same degree, proceed as follows: Reduce the equation to the form

$$y'^n + A_1 y'^{n-1} + \dots + A_n = 0.$$

in which A_1, &c., are of the form $\phi(y : x)$. Let $y = tx$ and find, in terms of t, the several values of y' or $t+xt'$, from the equation. Now $t+xt'=\phi t$, is an equation in which the variables can be separated. Solve each equation, and proceed as in the last.

27. The only equation of differences of the first order which can be generally treated, at present, is the form $\Delta u_x - P_x u_x = Q_x$, where P_x and Q_x are functions of x, or its corresponding form $u_{x+1} - P_x u_x = Q_x$. Supposing x to be an integer, which is what is usually required, let Σu_x denote $u_m + u_{m+1} + \dots + u_{x-1}$, where m is an arbitrary integer chosen to start from. Accordingly $\Delta\Sigma u_x = u_x$. The solution of $u_{x+1} - P_x u_x = Q_x$ is

$$u_x = P_m P_{m+1} \dots P_{x-1}\left\{C + \Sigma \frac{Q_x}{P_m \dots P_x}\right\}$$

28. Equations of differences in their most general form have solutions which appear to resemble the singular solutions of differential equations: but there are important points in which the resemblance fails. ('Differential Calculus—Library of Useful Knowledge,' p. 788.)

29. Let $y^{(n)}$ stand for the nth differential coefficient of y. The following expression

$$P_n y^{(n)} + P_{n-1} y^{(n-1)} + \dots + P_0 y$$

is absolutely integrable, independently of all relation between y and x, if

$$P_0 - P_1' + P_2'' - P_3''' + \dots = 0,$$

in which accents refer to complete differentiation with respect to x. And the integral is

$$P_n y^{(n-1)} + (P_{n-1} - P_n') y^{(n-2)}$$
$$+ (P_{n-2} - P'_{n-1} + P''_n) y^{(n-3)} + \dots$$

One remarkable case is this:—each term $P_m y^{(m)}$ is absolutely integrable when P_m is a rational and integral function of x of a degree lower than the mth. Thus y^{iv}, xy^{iv}, x^2y^{iv}, x^3y^{iv}, are all integrable functions; and xy^{iv}, x^2y^{iv}, are also integrable.

30. The equation $y^{(n)}=\phi x$ is not only completely integrable, but it may easily have all its intermediate differential equations found. For instance, suppose $y^{\mathrm{v}}=\phi x$. Multiply this successively by $1, x, x^2, x^3, x^4$, and, by the last section, we have five integrable equations, leading to the five differential equations of the fourth order which belong to $y^{\mathrm{v}} = \phi x$. Treat the first result in the same manner with $1, x, x^2, x^3$, the second with $1, x, x^2$, the third with $1, x$, and the fourth with 1, and we have the 10 equations of the third order. Proceed in the same way with the results, taking care never to let any multiplication enter which raises the coefficient as high as the order of differentiation which it accompanies, and then will appear successively 10 equations of the second order, 5 of the first, and finally the original primitive.

31. The following theorems will sometimes be of use. Let P_n stand for $\int x^n \phi x dx$. Then the nth integral of ϕx, or $\left(\int dx\right)^n \phi x$, is the following series divided by $1.2.3 \dots (n-1)$

$$x^{n-1} P_0 - (n-1)x^{n-2} P_1 + (n-1)\frac{n-2}{2} x^{n-3} P_2 - \dots$$

$$\text{and } (m+1)\int x^m P_n dx = x^{m+1} P_n - P_{m+n+1}$$

If the integrations in the last section be made by this last rule as they arise, the results will be given in terms of P_0, P_1, &c., and there will be no difficulty about the constants, which in the ordinary mode may appear to enter in too great numbers.

32. There are very few cases of equations of higher orders than the first which can be integrated in general terms. The equation $y''=\phi y$ gives

$$y'^2 = c + 2\int \phi y dy$$

which is integrable. Again, $y''+Qy'^2=R$, Q and R being functions of y, gives

$$x = \int \frac{W dy}{\sqrt{(2\int RW^2 dy)}} \text{ where log. } W = \int Q dy$$

and, by a change of the independent variable, $y''+Py'+Qy'^2=0$ gives, if P and Q be functions of x,

$$y = \int \frac{W dx}{\sqrt{(2\int QW^2 dx)}} \text{ where log. } W = -\int P dx.$$

33. The term *linear* equation is generally applied to one of the form

$$y^{(n)} + P_1 y^{(n-1)} + \dots + P_n y = 0$$

in which P_1 &c. are functions of x only. If a solution be found which has not n distinct arbitrary constants, it is not the most complete solution, but is called a *particular* * solution. It is a most important property of the linear equation that if n distinct particular solutions can be found, say $y=Y_1$, $y=Y_2$, &c., then the complete solution is

$$y = C_1 Y_1 + C_2 Y_2 + \dots + C_n Y_n$$

where C_1, C_2, &c., are any arbitrary constants.

34. The most remarkable case is that in which the coefficients are constants, as in $y^{(n)} + a_1 y^{(n-1)} + \dots + a_n y = 0$. If the equation $k^n + a_1 k^{n-1} + \dots + a_n = 0$ have n unequal roots, α, β, γ, &c., the general solution is

$$y = A\epsilon^{\alpha x} + B\epsilon^{\beta x} + C\epsilon^{\gamma x} \dots\dots$$

but if there should be, say m roots equal to α, the term which must belong to α in the solution is of the form

$$(A_0 + A_1 x + \dots + A_{m-1} x^{m-1})\,\epsilon^{\alpha x}$$

A pair of imaginary roots, $\mu \pm \nu\sqrt{-1}$, contributes to the solution the term

$$\epsilon^{\mu x}(K \cos \nu x + L \sin \nu x)$$

Letters introduced without specific mention mean arbitrary constants.

35. The most remarkable particular case of the preceding is

$$y'' + a^2 y = 0 \qquad y = K \cos ax + L \sin ax$$
$$= B \cos (ax + A)$$

No one differential equation is of so much importance as this.

36. When the equation is linear in all but an independent term, as

$$y^{(n)} + P_1 y^{(n-1)} + \dots + P_n y = X$$

X being a function of x, its solution can be deduced from that of the linear form, in which $X=0$, by a method the importance of which will justify some account of it in a separate article. [VARIATION of PARAMETERS.] We give the following result of it: $y''+a^2y=X$ gives

$$a\,y = \sin ax \int X \cos ax dx - \cos ax \int X \sin ax dx$$
$$+ K \cos ax + L \sin ax.$$

37. The completed linear form (take the second order for an instance) $P_0 y'' + P_1 y' + P_2 y = X$ can be integrated (§ 29) one step if both sides be multiplied by the factor M, which satisfies the purely linear equation

$$MP_2 - (MP_1)' + (MP_0)'' = 0$$

This is another differential equation of the same order, but the difficulty is much reduced by it. The general solution of the last is not wanted; any particular solution will do. That is, if a particular solution of every linear equation could be found, the general solution of every completed linear equation could be deduced. And it will generally happen that when one particular solution can be found, to make an integrating factor, enough of them can be found to give the complete solution of the original equation.

38. The form $\phi(y, y', y'')=0$, in which x is wanting, may be reduced to an equation of the first order, by making $y'=z$, when it becomes

---

* The student must not be discouraged by finding that he does not succeed in solving cases which require detached artifices in the same manner as the writer of the elementary work before him. The art of solving equations is made evident: the art of constructing equations which can be solved is behind the curtain. There are few or no mathematical works, with many examples, to the writers of which the proverb may not be applied, that "those who hide know where to find."

* The word particular is here opposed to general. Note this, because some writers have used *particular solution* to signify what is now generally called *singular solution*.

$\phi(y, z, z\,dz : dy)$. If z or y' be thence found in terms of y, the variables can be immediately separated: if y be found in terms of z, we eliminate z between $y=\psi z$ as found and $x=\int(\psi' z\,dz : z)$.

39. As an *à priori* mode of constructing linear equations and their solutions, note the following: If $\phi(x, y, y', \ldots y^{(n)})$ have for its solution $y=\psi(x, a, b, c, \ldots)$, a, b, c, &c., being arbitrary constants, and if P_0, P_1, P_2, &c., be the differential coefficients of ϕ with respect to y, y', y'', &c., considered as independent variables (with ψ substituted in them instead of y: then the solution of the linear equation

$$P_0 u + P_1 u' + P_2 u'' + \ldots \; P_n u^{(n)} = 0$$

is

$$u = A\psi_a' + B\psi_b' + C\psi_c' + \ldots\ldots$$

A, B, &c., being new arbitrary constants.

40. If to an equation of the nth order, all the n equations of the $(n-1)$th order can be found, each with an arbitrary constant, there is no occasion for any further integration. For if $y', y'', \ldots y^{(n-1)}$ be eliminated between the n equations, the result will be the complete primitive.

41. The purely linear equation, or indeed any one which is homogeneous with respect to y, y', y'', &c., can be lowered one order by assuming log. $y=\int z\,dx$, or $y=\epsilon^{\int z\,dx}$ (we have used the former, as more convenient to print). If this be done with $P_0 y'' + P_1 y' + P_2 y = 0$, it gives

$$P_0 z' + P_0 z^2 + P_1 z + P_2 = 0.$$

42. In this way the solution of $y''=\phi x\,.\,y$ is connected with that of $z'+z^2=\phi x$. When $\phi x = ax^m$, it is called Riccati's equation, and it can be integrated in finite algebraical terms whenever $m=-4k:(2k\pm 1)$, k being a positive integer.

43. If only a particular solution of $y''+Py'+Qy=0$ can be found, then the general solution of $y''+Py'+Qy+R=0$ can be found from it. Let $y=Y$ be the particular solution of the first, and let log. $W=\int P\,dx$: the general solution of the second is

$$y=-Y\int\frac{\int RYW\,dx}{Y^2W}\,dx.$$

44. If $\phi(x, y, y', y'')=0$ would become homogeneous with respect to x and y, by considering y, y' and y'' as of the dimensions $n, n-1, n-2$, assume $y=x^n u$, $y'=x^{n-1}v$, $y''=x^{n-2}w$, which reduces the equation to the form $\psi(u, v, w)=0$. Then deduce

$$(w-\overline{n-1}\;v)\,du=(v-nu)\,dv.$$

and substitute for w its value in terms of u and v. If this equation of the first order can then be integrated, giving, say $\chi(u, v)=0$, we have to complete the process by integrating $\chi(yx^{-n}, y'x^{-(n-1)})=0$.

45. To destroy the second term of $y''+Py'+Qy+R=0$ proceed as follows. Let $\xi=\int\epsilon^{-\int P\,dx}dx$, and find x in terms of ξ. Then we have

$$\frac{d^2y}{d\xi^2}+(Qy+R)\,\frac{dx^2}{d\xi^2}=0$$

46. Any number of simultaneous equations which leave only one independent variable can be reduced to equations between two variables. For instance, let there be three equations between x, y, z, t, and differential coefficients of x, y, z, with respect to t. Now, looking upon x, x', &c. y, y', &c. (excluding z, z', &c.), as so many independent quantities, differentiate the three equations with respect to t. There are then introduced *two* new differential coefficients of x and y, and *three* new equations: or the number of equations gains one upon the number of quantities. Repeat the process, and the same thing happens again, and so on. Consequently a step must arrive at which the number of equations is made one more than the number of quantities. All the quantities can then be eliminated, and there results one equation between z, z' &c., and t. The same thing may be done with x and y. The process will also reduce the number of equations to as many as there are independent variables, whatever that number may be. The order of the result is the sum of the orders of the original equations.

47. In the simple case of $Ay'+Bz'+C=0$, $Py'+Qz'+R=0$, when A, P, &c., are functions of x, y, z, and z' is $dz : dx$, &c., we may proceed by eliminating y' and forming say $z'=M$, a function of x, y, z. Hence $z''=M'_x+M'_y\,y'+M'_z\,z'$, from which we may eliminate y and y' by the original equations, and thus produce an equation of the second order to determine z in terms of x. And the same for y in terms of x.

48. Let t be the independent variable, and let

$$x'=A_1x+B_1y+C_1 \qquad , y'=A_2x+B_2y+C_2$$

functions of t only. Determine θ and z from

$$\theta'=A_2\theta^2+(A_1-B_2)\,\theta-B_1$$
$$z'=(A_1+A_2\theta)\,z+C_1+C_2\theta$$

θ will generally be a function of double value; let θ_1 and θ_2 be its two values, and z_1 and z_2 the corresponding two values of z. Finally, determine x and y from

$$x+\theta_1 y=z_1$$
$$x+\theta_2 y=z_2.$$

49. When the forms are

$$x''=A_1x+B_1y+C_1 \quad , \quad y''=A_2x+B_2y+C_2$$

A_1 &c. being constants (a case which is often useful) determine the two values of θ from

$$B_1+B_2\theta=(A_1+A_2\theta)\,\theta$$

and the two values of z from

$$z''=(A_1+A_2\theta)\,z+C_1+C_2\theta$$

and find x and y from $x+\theta_1 y=z_1 \quad , \quad x+\theta_2 y=z_2$.

50. Also, when the simultaneous equations are linear, with constant coefficients, proceed as follows. Say there are four variables, x, y, z, t; and three equations. Assume $x=\epsilon^{at}$, $y=b\epsilon^{at}$, $z=c\epsilon^{at}$, and substitute: the result will be, after division by ϵ^{at}, three equations of the form $\phi(a, b, c)=0$, in which b and c only enter in the first degree. Hence the values of a can be found by an equation whose degree is the sum of the orders of the original equations, with one value of b and c for each value of a. Let the values be $a_1, a_2, b_1, b_2, c_1, c_2$, &c., then the complete solution is

$$x=C_1\epsilon^{a_1t}+C_2\epsilon^{a_2t}+\ldots\ldots$$
$$y=C_1b_1\epsilon^{a_1t}+C_2b_2\epsilon^{a_2t}+\ldots\ldots$$
$$z=C_1c_1\epsilon^{a_1t}+C_2c_2\epsilon^{a_2t}+\ldots\ldots$$

C, &c. being arbitrary constants.

51. Whenever the solution of a differential equation depends upon that of an ordinary equation, and supposing the roots to be all different, the form of the solution is

$$x=C_1\,\phi(a_1t)+C_2\,\phi(a_2t)+\ldots\ldots$$

the solution, though still a solution, ceases to be the complete solution when there are any sets of equal roots. If there be m roots equal to a, and if $\phi' x, \phi'' x$, &c., be the successive differential coefficients of ϕx, this set of roots contributes to the value of x the terms

$$K\,\phi(at)+K_1\,\phi'(at)\,.\,t+\ldots\ldots+K_{m-1}\,\phi^{(m-1)}(at)\,.\,t^{m-1}$$

of which a particular case has been seen in § 34.

52. We now look at one equation with three variables, two of which are therefore independent. Let $X\,dx+Y\,dy+Z\,dz=0$ be the equation. This may have arisen direct from $\phi(x, y, z)=c$, without alteration or loss of factors, &c.: and this will be the case when $X'_y=Y'_x$, $Y'_z=Z'_y$, $Z'_x=X'_z$, and then only. To return to the primitive, integrate $X\,dx+Y\,dy$ (§ 10) as if z were constant, and let the result be P. The integral of $X\,dx+Y\,dy+Z\,dz$ is then

$$P+\int(Z-P'_z)\,dz$$

Or thus: when the criteria are satisfied, the integral (omitting the usual commas, to save room) of

$$\phi(xyz)\,dx+\chi(xyz)\,dy+\psi(xyz)\,dz \quad \text{is}$$
$$\int_a^x\phi(xyz)\,dx+\int_b^y\chi(ayz)\,dy+\int_c^z\phi(abz)\,dz$$

in the first of which y and z are treated as constants, and z in the second.

53. If the criteria be not satisfied, a factor M may possibly exist, such that $MX\,dx+MY\,dy+MZ\,dz$ shall be integrable. But this cannot happen unless the following criterion be satisfied:

$$Z(X'_y-Y'_x)+X(Y'_z-Z'_y)+Y(Z'_x-X'_z)=0$$

and the factor, when this is satisfied, must satisfy any two of the three equations.

$$M(X'_y-Y'_x)+XM'_y-YM'_x=0$$
$$M(Y'_z-Z'_y)+YM'_z-ZM'_y=0$$
$$M(Z'_x-X'_z)+ZM'_x-XM'_z=0$$

But if the criterion be not satisfied, then there is no equation whatsoever between x, y, z, which always produces $X\,dx+Y\,dy+Z\,dz=0$.

54. The equation $X\,dx+Y\,dy+Z\,dz=0$, when produced from $\phi(x, y, z)=c$, is the equation of a family of surfaces, the individuals of which are defined by the different values of c. That is to say, any point of one of these surfaces being taken, and any other point infinitely near to it, the equation is satisfied by x, dx, &c., as derived from these points. But when the criterion is not satisfied, then $X\,dx+Y\,dy+Z\,dz$ still belongs to any surface in the following limited sense. On any surface, and through any point of it, a curve may be drawn such that the equation $X\,dx+$ &c. is satisfied if the two contiguous points first named be taken *on that curve.*

55. When there are three variables and two equations, with two constants, as in $\phi(x, y, z, a, b)=0$, $\psi(x, y, z, a, b)=0$; the most ready theoretical mode of imagining the differential equations formed is the reduction to the form $a=\Phi(x, y, z)$, $b=\Psi(x, y, z)$, and differentiation. Two equations of the form $P\,dx+Q\,dy+R\,dz=0$ are thus produced; from which, by combination, may be derived an infinite number of pairs of the same kind, answering to the infinite variety of pairs which can be produced from the primitive equations. This corresponds with the obvious geometrical fact that one curve may be the intersection of an infinite number of different pairs of surfaces.

56. A partial differential equation, such as $\phi(x, y, z, z'_x, z'_y)=0$, belongs to an infinite number of surfaces distinguished by the forms of the arbitrary function which enters into the solution. The most general method of proceeding is as follows, which supposes that a particular solution is found having at least *two* new arbitrary constants. Let $f(x, y, z, a, b)=0$ be such a solution, and call it a *primary* solution. Make $b=\mathrm{F}a$, where $\mathrm{F}a$ is any function of a, at pleasure. Then the *general* solution is

$$f(x, y, z, a, \mathrm{F}a)=0,$$

in which a is a function of x, y, z, determined from

$$f'_a(x, y, z, a, \mathrm{F}a) = 0.$$

The arbitrary character of $\mathrm{F}a$ introduces an arbitrary function.

The geometrical meaning of this is as follows: The primary solution, a and b being independent, is the equation of an infinite number of families of surfaces: when b is made $=\mathrm{F}a$, the equation is restricted to one of these families; and each case of the general solution answering to one form of $\mathrm{F}a$, is the equation of the surface which touches every individual of the family throughout the extent of some curve. Every surface which comes under the general solution is then tangent to a whole family of primary solutions. But it must not be forgotten that every primary solution is also a case of the general solution, so that there is no primary solution but what is also tangent to a whole family of other primary solutions.

57. There is generally a surface which touches all the surfaces of the general solution, and is a singular solution of the partial differential equation, not contained in the general solution. It is found by substituting in $f(x, y, z, a, b)=0$, values of a and b derived from

$$f'_a(x, y, z, a, b) = 0, \qquad f'_b(x, y, z, a, b) = 0.$$

We shall illustrate this subject in VARIATION OF PARAMETERS.

Let $\mathrm{X}u'_x + \mathrm{Y}u'_y = \mathrm{U}$, where X, &c. may be functions of x, y, and u. The integration entirely depends upon that of the following system of ordinary differential equations:—

$$\frac{dx}{\mathrm{X}} = \frac{dy}{\mathrm{Y}} = \frac{du}{\mathrm{U}}$$

if these can be integrated, and the results reduced to the form $a=\alpha(x, y, u)$, $b=\beta(x, y, u)$, α and β being functional symbols, then the complete integral of the given equation is $\beta=f\alpha$, or

$$\mathrm{F}\left\{\alpha(x, y, u), \beta(x, y, u)\right\} = 0$$

f and F being any functions whatever.

This may be extended to any number of variables. Thus if

$$\mathrm{X}u'_x + \mathrm{Y}u'_y + \mathrm{T}u'_t = \mathrm{U},$$

let the solution of

$$\frac{dx}{\mathrm{X}} = \frac{dy}{\mathrm{Y}} = \frac{dt}{\mathrm{T}} = \frac{du}{\mathrm{U}}$$

be obtained in the form $a=\mathrm{P}$, $b=\mathrm{Q}$, $c=\mathrm{R}$, where a, b, c, are the constants introduced by integration, and P, Q, R, are functions of x, y, t, independent of those new constants. The complete solution of the partial differential equation is $\mathrm{F}(\mathrm{P}, \mathrm{Q}, \mathrm{R})=0$, F being any function whatever.

59. The same mode holds when there are several equations with two more variables than equations, if the multipliers of differential coefficients be the same in all. Thus the system $\mathrm{X}u'_x + \mathrm{Y}u'_y = \mathrm{U}$, $\mathrm{X}v'_x + \mathrm{Y}v'_y = \mathrm{V}$, $\mathrm{X}w'_x + \mathrm{Y}w'_y = \mathrm{W}$, can be integrated if the system

$$\frac{dx}{\mathrm{X}} = \frac{dy}{\mathrm{Y}} = \frac{du}{\mathrm{U}} = \frac{dv}{\mathrm{V}} = \frac{dw}{\mathrm{W}}$$

can be integrated in the form $a=\mathrm{P}$, $b=\mathrm{Q}$, $c=\mathrm{R}$, $e=\mathrm{S}$, described as before. The complete solution is the system

$\mathrm{F}_1(\mathrm{P}, \mathrm{Q}, \mathrm{R}, \mathrm{S})=0$, $\mathrm{F}_2(\mathrm{P}, \mathrm{Q}, \mathrm{R}, \mathrm{S})=0$, $\mathrm{F}_3(\mathrm{P}, \mathrm{Q}, \mathrm{R}, \mathrm{S})=0$, where F_1, &c., are symbols of any functions whatever.

60. Nearly all that can be done in this part of the subject depends upon cases of three variables and their connection with surfaces. The following notation is in universal use: Having z, a function of x and y, let z'_x and z'_y be denoted by p and q, and the second differential co-efficients z''_{xx}, z''_{xy}, z''_{yy}, by r, s, and t.

61. Let $z=px+qy+f(p, q)$ be the equation. A primary solution is $z=ax+by+f(a, b)$. The general solution, deduced as in § 56, gives the equation of all developable surfaces, if f be arbitrary. The form $q=\phi p$, ϕ being a given function, has $z=ax+\phi a.y+b$ for a primary solution, and belongs to a particular class of developable surfaces. Both these equations, and all developable surfaces, satisfy the equation $rt-s^2=0$.

62. For the method of dealing generally with the equation of the second degree, $\mathrm{R}r+\mathrm{S}s+\mathrm{T}t=\mathrm{V}$, see 'Differential Calculus,' in 'Library of Useful Knowledge,' p. 719. It would hardly yield a short account for a work of reference.

63. Let $r=a^2t$. Of this very important equation the complete solution is

$$z=\phi(y+ax)+\psi(y-ax).$$

ϕ and ψ being any functions.

64. Let $z=\phi(p, q)$. Solve the common differential equation $y=\phi(ay', y')$, giving, say $y=\psi(x, b)$. Then $z=\psi(y+ax, b)$ is a primary solution of the given equation.

65. Let $\phi(p, x)=\psi(q, y)$. Let $\phi(p, x)=a$, $\psi(q, x)=a$, give $p=\Phi(x, a)$ $q=\Psi(x, a)$. Then eliminate a from

$$z=\int\cdot\left\{\Phi(x, a)\,.\,dx+\Psi(y, a)\,.\,dy\right\}+\chi a$$

$$0=\frac{d}{da}\int\left\{\Phi(x, a)\,.\,dx+\Psi(y, a)\,.\,dy\right\}+\chi' a$$

χa being any function whatever of a.

66. Let X, Y, Z, be three new variables, and let P, Q, R, S, T be the differential coefficients of Z: that is $\mathrm{Z}'_x=\mathrm{P}$, $\mathrm{Z}'_y=\mathrm{Q}$, $\mathrm{Z}'_{xx}=\mathrm{R}$, &c. For the equation $\phi(x, y, z, p, q, r, s, t) = 0$, substitute as follows:—

For x	P
y	Q
z	$\mathrm{PX}+\mathrm{QY}-\mathrm{Z}$
p	X
q	Y
$px+qy-z$	Z
r	$\frac{\mathrm{T}}{\mathrm{RT}-\mathrm{S}^2}$
s	$\frac{-\mathrm{S}}{\mathrm{RT}-\mathrm{S}^2}$
t	$\frac{\mathrm{R}}{\mathrm{RT}-\mathrm{S}^2}$

If the resulting equation can be integrated into $\mathrm{Z}=\psi(\mathrm{X}, \mathrm{Y})$, then the original equation is integrated by eliminating X and Y from

$$x=\mathrm{P} \quad y=\mathrm{Q} \quad z=\mathrm{PX}+\mathrm{QY}-\mathrm{Z}$$

67. Linear equations of differences with constant coefficients, such as

$$u_{x+3} + au_{x+2} + bu_{x+1} + cu_x = 0$$

may be solved in a manner corresponding to linear differential equations by assuming $u_x = m^x$ and obtaining its particular solutions by means of $m^3+am^2+bm+c=0$.

We have not touched on the application of the calculus of operations, nor on that of definite integrals, subjects which are now of very great importance. On these points see OPERATION, INTEGRALS, DEFINITE. See also FUNCTION, ARBITRARY.

It must be noticed that a great portion of the most important part of the subject of differential equations cannot enter in any work on pure mathematics. The physical subjects of gravitation, heat, electricity, &c., depend so much on certain differential equations that, by common consent, the details are referred to works on these subjects, and do not appear separately.

EQUATIONS, FUNCTIONAL. In this case the question is to find the form of a function which will satisfy certain conditions. For instance $\phi(x^2)=\phi x + 1$. Here the question asked is, what is that algebraical expression which will be increased by 1, *whatever may be the value of* x, by changing x into x^2. [FUNCTIONS, CALCULUS OF.]

EQUATOR and ECLIPTIC, the two principal circles of the sphere. The first is that circle of the apparent celestial sphere which is in all points equally distant from both poles; the second, the circle through which the sun appears to move. The equator is so called from being the circle on the arrival of the sun at which the day and night become equal. The ecliptic derives its name from being the circle on which (or near which) the moon must be in the case of an eclipse. [SPHERE, DOCTRINE OF THE.]

EQUATOR, MAGNETIC. [MAGNETISM.]

EQUATORIAL INSTRUMENT. This name is generally given to astronomical instruments which have their principal axis of rotation in the direction of the poles of the heavens. When the purpose of a machine of this nature is simply to carry a telescope, it has been called a *machine parallactique* or *parallatique* by the French, and sometimes *polar axis* by English writers; but we shall include both in this article.

The complicated system of circles which formed the *astrolabe* of Hipparchus, described by Ptolemy ('Almagest.,' lib. v. cap. i.), was made moveable on two pins, which marked the places of the pole in a metallic meridian circle, and thus may be called in some sort an equatorial. There is an excellent plate of the astrolabe in the title-page of Halma's translation, tom. i. This instrument and the copies which were made of it afterwards, according to Ptolemy's description, by the Arabs and by Walther of Nuremberg, were designed for observing the longitude and latitude of a heavenly body directly. The *torquetum* of Regiomontanus was for the same purpose, but surfaces were used instead of axes to determine motions, but we know not whether it was ever actually made. Tycho seems first to have seen the immense superiority of the simpler instrument, which sufficed for determining right ascension and declination: and the genuine equatorial is therefore due to him. In his 'Astronomicæ Instauratæ Mechanica,' Noribergæ, 1602, we find the figures and descriptions of three 'equatorial armillæ' of different sizes and constructions; in one, the diameter of the meridian circle was 7 cubits, or 10½ feet. (For Tycho's equatorials see ASTROLABE.) In the 'Rosa Ursina' of Scheiner, Bracciani, 1626–30, p. 350 et seq., there is a plate and description of an equatorial mounting, invented by Gruenberger, to be used with a lens or telescope, for forming an image of the sun—the mode of observation then in vogue—or, with a telescope, in the modern manner for viewing the moon, stars, and other phenomena. Gruenberger's equatorial is almost identical with that described and figured by Cassini as his *machine parallactique*, 'Mémoires de l'Académie,' 1721, p. 18, and which is also drawn and described under the same name by Bailly, 'Histoire de l'Astronomie Moderne,' vol. i. p. 601, plate v., fig. 38; and by Lalande, 'Astronomie,' 1792, § 2400, et seq., plate xxiv. In 1674 Hooke published his 'Animadversions' on the first part of the 'Machina Cœlestis' of Hevelius. In this remarkable tract he describes, p. 67 et seq., tab. 2, fig. 15, the polar axis, on which he proposes to fix his quadrant for measuring intermutual distances, and "the watch-work, which is to make it move round in the same time with the diurnal revolution of the earth." * The regulator of the watch-work is a ball and string, describing a conical surface. When so near an approach had been made to this great desideratum in telescope-mounting, it is somewhat remarkable that nearly 150 years should have elapsed before it was realised. The astronomical sector with which Flamsteed observed at Greenwich from 1676 to 1689 bears so strong a resemblance to the quadrant and stand described in Hooke's tract, that we are inclined to attribute the merit of its contrivance to Hooke, particularly as he recommends the artificer Tompion as "having been imployed by him to make that which he had." Flamsteed's instrument was a sextant mounted upon a polar axis; and a description of the instrument, with a plate, will be found in the 'Historia Cœlestis,' vol. iii., p. 103.

The next step in the construction of the equatorial was made by Römer, to whom we owe the transit and circle, and whose merits as an astronomical mechanic surpass even his great countryman Tycho. According to Horrebow, 'Basis Astronomiæ,' p. 39, tab. 1, the equatorial of Römer was erected about 1690. Here we have the second essential to the instrument, a telescope mounted on a cross axis, which is placed at right angles to the polar axis; (this is sometimes called the *declination axis*, from its carrying the declination circle, or *transit axis*, from its analogy to the transit). In this construction the telescope can be pointed in every direction, and we have heard Römer's general idea recommended by a very competent judge as that which he would now follow in mounting a 20-foot telescope. Graham's differential sector and Sisson's equatorial are described in Vince's 'Practical Astronomy,' § 136 and 140, with figures; but the author has committed an error in his description. Graham's astronomical sector is supported like Hook's quadrant and Flamsteed's sextant (see Smith's 'Optics' § 885, book 3, chap. 9); but, in explaining the instrument, Smith uses a figure for illustration which Vince has copied as the actual instrument. It is in the Royal Observatory.

A portable equatorial stand for carrying a reflecting telescope was invented by Short, and is described and figured in the 'Phil. Trans.' for 1749. This must have been a very ricketty affair, judging from the plate. In 1771 Nairne gave a description and figure of a much better instrument in the same work; and in 1772, or 1773, P. and J. Dollond published an account of a "universal equatorial instrument, or portable observatory," which in firmness and contrivance is very similar to that of Nairne. This construction, with some slight variations, was followed by Ramsden, in a portable equatorial made for Sir George Schuckburgh, in 1779. All these portable equatorials labour under this serious defect; the telescope cannot be pointed on the same star in reversed positions, nor upon any star within 30° or 40° of the pole. Lalande, in his 'Astronomie,' § 2413, pl. xxvi., gives an account of an equatorial made by Megnié, for the President de Saron, in which this difficulty is overcome by fixing the telescope at the extremity of the cross axis, so as to overhang the hour circle. A very beautiful universal equatorial, in which the same position of the telescope is adopted, was constructed by Troughton, a figure and description of which will be given at the latter end of this article. There are some equatorials by Nairne and Adams which have a telescope at one end of the cross axis, but we are not aware that they have been figured or described.

A new era in the equatorial commences with the construction by Ramsden for Sir George Shuckburgh in 1791, which is elaborately described with plates in the 'Phil. Trans.' for 1793. In this instrument the telescope and the declination circle form a complete and symmetrical transit circle, which is supported at its extremities by two assemblages each of three long parallel brass tubes forming the polar axis. The upper ends of these tubes are set into a circular open frame, from the centre of which the top pivot rises, and their lower ends rest on the base of an inverted cone, which has the bottom pivot at its vertex. The polar axis is so long as to allow the telescope to revolve completely, and the object-glass is large enough to give a sight of the pole through the upper circle. The general form of this instrument is followed, with some variations, in almost every considerable English instrument which has been since made with the view of being used to measure with the circles. All have had a long polar axis supported at the extremities, and divided in the direction of its length into two limbs or cheeks, within which the declination axis is supported as a transit between its piers. Of this kind are the equatorials of Cambridge and Brussels, as well as of Armagh, described in Rees's 'Cyclopædia,' and of Camden Hill, described by Troughton, and figured in the 'Phil. Trans.' for 1825, in the Preface to Herschel and South's Observations of Double Stars.

After Fraunhofer had succeeded in forming larger and better achromatic object-glasses than had hitherto been thought possible, he chose for a stand one which is in principle identical with the *Machine Parallatique*, only having the telescope hung on one side, exactly as in the portable equatorial of Megnié. To these he applied a very ingenious clock movement, which greatly facilitated the optical use of the instrument, and rendered it a better micrometrical measurer than had previously existed. To prevent the telescope from bending, Fraunhofer applied a system of balance weights, which were, we believe, invented or brought into extensive use by Reichenbach. It would probably have been better if he had made the telescope stiff, by bracing a form, and had omitted the balance weights for the telescope altogether. It is evident, from their construction, that the least jar or roughness in handling the telescope must set the weights in motion, and consequently ruin the action of the object-glass until they come to rest; and it is not worth while to purchase a little useless accuracy in the measurement with the circles at such a cost. There is considerable inconvenience in this construction; for example, in many positions a star cannot be followed from one side of the meridian to the other without bringing the telescope over, that is, turning the polar axis and the telescope each of them half round. This is particularly disagreeable in the measurement of double stars, which ought, if possible, to be observed near the meridian. There is, perhaps, a little more inconvenience in giving small motions to the telescope; but neither this nor the impossibility of using reversed observations in a majority of instances is of much consequence. On the other hand, when the workmanship and material and engineering are good, an instrument of this form may be expected to stand better in adjustment, and to admit of larger dimensions, and to require less room, than any other.

The most celebrated of Fraunhofer's equatorials is one which is erected at Dorpat, and has been described by Professor Struve. ('Beschreibung des grossen Refractors von Fraunhofer,' Dorpat, 1825, folio, with plates.)

Some enormous telescopes have been mounted on this principle: one carrying the largest achromatic telescope we believe in existence, of 14 inches aperture and 25 feet focal length, was erected at Markree Castle, county of Sligo, for E. J. Cooper, Esq., by Mr. Grubb, of Dublin. The tube of the telescope was constructed under the direction of Mr. Cubitt, and is a capital step in the art of applying large telescopes. The form is that of a very long barrel. T bars of wrought iron extend longitudinally from the object to the eye end, the edge bars being directed towards the centre, and these, after they are connected crosswise by strong rings, are covered with iron plate, which is $\frac{1}{4}$ inch thick in the centre and $\frac{1}{16}$ inch at the extremities. The stiffness of this tube is more perfect than would be readily believed without actual examination, and we see no reason to doubt that a telescope, of at least twice these dimensions, may be mounted with success, so far as the tube is concerned, whenever such an object-glass can be procured. In most of the other large equatorials which we have seen, the telescope is the weakest part; and as it is the habit of many observers to move their instruments by laying hold of the eye end, it is desirable, for this and for some better reasons, to have it as stiff as possible. The equatorial erected in 1838 at the Royal Observatory, Greenwich, was also mounted by Mr. Grubb. The object-glass, the definition of which is very good, was made by M. Cauchoix of Paris, and was presented to the Observatory by the late Rev. R. Sheepshanks. It is nearly 7 inches in clear diameter, and of 8 feet focal length. The telescope is on one side of the axis, and is counterpoised by weights on the other, as in Fraunhofer's method. The hour circle and declination circle are of small size and are chiefly used for setting the instrument. In an equatorial made to carry a 20-foot telescope, constructed for the observatory of Cambridge, at the expense of his grace the Duke of Northumberland, and of Ramsden's form, though with many peculiarities and improvements, Mr. Airy has employed a square wooden tube. Mr. Dollond has made several equatorials on Sisson's construction, which answer very well. The polar axis in these is square, and composed of four strong slabs of wood, making a sort of tube, a little tapered towards the extremities. This is found to be abundantly stiff and firm, at least up to the dimensions which have been tried, namely, for telescopes of from 10 to 12 feet focal length.

Among the astronomical instruments in the Great Exhibition of 1851 were several equatorials, which are minutely described in Mr. Glaisher's masterly report (Class X.). We select a few particulars. In Mr. Ross's large equatorial, the telescope had an aperture of $11\frac{1}{4}$ inches, and a focal length of 18 feet. The hour circle was 2 feet 8 inches in diameter, and the declination circle 2 feet 8 inches. The instrument was supported on a round cast-iron pillar, 10 feet 9 inches in height, 2 feet 3 inches in diameter at the bottom, decreasing to 1 foot at the top, and formed of two portions, fastened together at the height of 4½ feet from the bottom of the base by eight screw bolts and nuts passing through flanges 3 inches in width from the shafts of the column, thus affording the means of an approximate meridian adjustment; the base of the pillar was 9 feet in diameter. The polar axis was of cast iron, 6 inches in diameter and 5 feet in length, connected to the declination axis by a flange 18 inches in diameter. The inner male declination axis is 3½ feet long between its bearings, and the outer or hollow axis was 7 inches in diameter, and both of cast iron. The inner axis and its flange formed one casting with the central hollow cylinder, to the flanges of which the corresponding gun-metal flanges of the telescope were bolted. The tube was of copper. The fitting bearings of the declination axis were cylindrical, and the axis was secured by a steel collar, 4 inches in length, fastened by cross pins to the male centre, at the end to which the circle was fixed. In the inner axis there was a counter-sunk cavity to receive this collar, and a second similar cavity of large diameter to receive a steel plate fastened against the end of the steel collar by eight steel screws, by which means the end-strake of the axis was adjusted. The declination circle was of gun-metal, regulated by an endless screw with an excentric lever attached to a dove-tail slide for gearing, and a pair of bevelled wheels at either end for Hooks' joint adjusting rods. There were also two other radial arms with clamp screws for securing the telescope to the circle. The upper part of the polar axis fitted into a coupling-block, with a hemispherical bottom, supported by an angular projection from the top of the pillar, which had a corresponding cavity, the whole being bound together by bolts and nuts with spherical faces, bearing in corresponding cavities their washers; the bolts passing freely through the holes. The lower end of the polar axis consisted of a hemisphere of hardened steel, bearing on a hardened steel die, surrounded by an oil-cup attached to dove-tail slides, with motions in rectangular directions, supported by a very strong bracket projecting from the main column and applicable to the final adjustment of the polar axis. The hour-circle was moved by a weight and train of wheels, regulated by a Siemen's governor, the ball being suspended by four springs.

---

* Hooke asserts that a clock with a circular pendulum was invented by him in 1665, and complains that Huyghens had published a description of this (in 1674) "without naming him at all as concerned therein." Huyghens says that he invented the clock with a circular pendulum about the same time that he applied the oscillating pendulum, that is, sixteen years before the date of his book, and that several clocks of this description had been been made, "non sine successu," in the mean time. Both Hooke and Huyghens promised to give a complete description of this clock at another opportunity.

Mr. Simms exhibited an equatorial generally of the Fraunhofer form, the only peculiarity being in the declination axis, which was not covered up, but open and exposed between its two supports. The open part was cylindrical, and could be set horizontal by a striding level, similar to that of a transit instrument. Mr. Simms had also a small equatorial, adapted to the latitude of London, but without clock motion. The instrument was said to be inexpensive, and, considering its size, was effective. Mr. Dollond exhibited a portable equatorial supported on a strong folding tripod with divided circles, a finder, levels, and eyepieces. The instrument was said to be well adapted for seeking for comets. Merz and Sons (Bavaria) had an equatorial with the polar axis adjustible within certain limits, so as to adapt it as a portable instrument, and to be applicable to different latitudes within those limits. The focal length of the telescope was four feet, and the object-glass had an aperture of four inches,—unusually large for this size of telescope, but, by admitting a large pencil of light, adapting it for faint objects.

In mounting a large telescope equatorially, it is not expedient to rest the pivots on small superficial bearings, or to relieve the weight by friction rollers, unless the axis of the rollers be made large. It appeared, in Mr. Cooper's equatorial and elsewhere, that when a heavy pressure was laid on a small bearing, the surfaces did not slip freely, but clung together as it were, causing small oscillations about the position of rest. Again, great care should be taken in following Sisson's construction, or that which we have described as Ramsden's, to provide against any twisting in the axis; simple flexure being of little importance. In Sisson's construction, the junction of the telescope and its cross axis should be very firm; in Ramsden's, the union of the two sides of the polar axis with the base should be such as to prevent all wriggling; and in both, the telescope ought to be very stiff, if it is likely to be roughly handled. To Ramsden's we should apply steadying rods. It is also better to rest the pivots of the declination axis in Ys than in collars; but if a collar is preferred, it should be formed of an upper and lower half, which can be adjusted to clasp the pivot close when the collar wears loose. After all possible precautions, accuracy is not to be expected from a large equatorial, when used as an instrument measuring with its circles, compared with those of moderate size. The equatorial by Troughton, at Armagh, carries a telescope of only 42 inches focal length and 2¾ inches aperture, with an hour circle of 5 feet, and yet the telescope is more powerful than the circles used. Large equatorials are required whenever optical power is wanted, as in the examination of nebulæ, noting occultations, &c., where the micrometer is alone required for measurements, as in observations of double stars, or determinations of the diameters and forms and constitutions of planets, and investigation of the systems of those which have rings, satellites, &c. In these respects Lord Rosse's large reflector erected at Parsonstown Castle, Ireland, deserves especial notice. The clear aperture is 6 feet, and the magnitude of reflecting surface is 28·274 square feet. Though used as a Newtonian telescope, the apparatus of suspension is so arranged that the instrument must be worked as an equatorial. [TELESCOPE.]

The adjustments of an equatorial instrument are easy enough to a person tolerably familiar with the management of other astronomical instruments; and the corrections which are to be applied to observations made with an unadjusted equatorial, ought not to present any difficulty to an astronomer acquainted with spherical trigonometry, and with the ordinary rules for determining the value of the coefficients. Still, as there are many persons who possess equatorially-mounted telescopes, and have not the knowledge or even the leisure to understand this subject thoroughly, we shall proceed to give directions which will enable any one to adjust his instruments with more than sufficient accuracy and without trouble.

We suppose the latitude of the place and the direction of the meridian to be approximately known; and we shall speak as if the instrument showed north polar distance, and the hour circle, when the sun is observed, read as an ordinary clock. Let the polar axis be placed nearly in the direction of the poles of the heavens. The adjustments proceed in the following order:—1st. The polar axis is placed at the altitude of the pole. 2nd. The indices of the declination circle are made to read 0, when the telescope points to the pole; this is sometimes called "correcting the collimation in declination," or "north polar distance." 3rd. The pole of the instrument is brought into the meridian, and as it has already been set at the proper altitude, it now coincides with the pole of the heavens. 4th. The line of sight of the telescope is made perpendicular to the declination axis; this is similar to the collimation adjustment in the transit. 5th. The declination axis is placed exactly at right angles with the polar axis, if the means of adjustment are allowed. 6th. The hour circle is made to read 0^h, when the telescope is in the meridian of the place.

1st. Observe any known star in north polar distance, and then turning the polar axis half round, observe the same star again; these observations should be as near the meridian as possible; and if the instrument is much out of adjustment, the star should not be very near the pole. Take the mean of the two observations, which is the distance of the star from the pole of the instrument, correct it for refraction, and then compare the result with the true north polar distance given by the Nautical Almanac, or computed from a standard catalogue. If the star be above the pole, and the instrumental north polar distance be *greater* than the true north polar distance, it is clear that the instrumental pole is farther from the star than is the pole of the heavens, or that it is too *low;* but if the instrumental north polar distance be *less* than the true north polar distance, then the pole of the instrument is too *high.* Correct this error by the proper screws for raising or depressing the polar axis, which may be done at once if the thread of the screw and the length of the polar axis be known.

2nd. Take half the difference of the above two observations; this is the index error of the declination verniers or microscopes, and they must be moved just so much in the proper direction by their adjusting screws, and set, if there be more than one, at their proper distances. The polar distance read off will now correspond with the true *instrumental* polar distance in every position of the instrument. Several pairs of observations should be taken, in order to ascertain these two errors with great accuracy before they are finally corrected and considered to be settled.

3rd. Turn the instrument six hours from the meridian either way, and observe the north polar distance of any known star not very near the pole nor yet near the horizon. Correct this for refraction. We will suppose the star observed to the east of the meridian, and that the observed distance exceeds that given by the Nautical Almanac or the standard catalogue; then the pole of the instrument is further from the star than is the pole of the heavens, or is to the west of its proper place; hence the upper pivot must be shifted to the east, or the lower pivot to the west, the proper quantity. In this, as in the former case, several stars should be used for greater accuracy; but there is no necessity for reversed observations, as the index error is already supposed to be corrected, or at least to be known, and therefore easily allowed for. The polar axis is now adjusted both in altitude and azimuth.

4th. Observe the transit of an equatorial star over the middle vertical wire or mean of the wires, note the time, and read off the verniers of the hour-circle. Turn the polar axis half round, and observe the same star a second time exactly as before. Now if the time between the two observations corresponds exactly to the difference between the two readings of the hour-circle, all is right; if not, it is evident that one of the transits has been observed too early, and the other too late, on account of the erroneous position of the wires. If the time elapsed be *greater*, by 6^s suppose, than the difference of the hour-angles, the first transit has taken place 3^s too early and the second 3^s too late. Set again upon the star and observe how far it appears to travel in 3^s; and then if the instrument is in the first position, move the wires this quantity in R.A. with the star, and *vice versâ* if the instrument be in the second position. The rule *mutatis mutandis* will apply to any case, and where there are no means of measurement and no mark, the adjustment must be made by repeated trials. With a micrometer in R.A., or with a mark, it may be performed with accuracy at once.

5th. This adjustment may be performed in two ways, either astronomically, or, when there is a level attached to the declination axis, mechanically. In the first case observe the transit of a star, not less than 45° from the equator, in reversed positions of the polar axis, exactly as in determining the collimation. Since an elevation of the west end of the declination axis causes the line of sight to describe a circle to the east of the pole, all the transits observed in that position will be too early, and *vice versâ* all will be too late when the east end is high. Again, if the west end is too high before reversing, the east is too high after reversing; so that an error of inclination has a different effect upon observations in reversed positions, and thus the interval is increased or diminished by twice the error of a single observation. The law of the error is that it varies as the tangent of the star's declination. Suppose the star observed to have 45° declination, and that the interval between the observations is, according to the clock, $3^m\ 8^s$, and according to the hour-circle only 3^m. It is evident that the first observation was 4^s too early and the second 4^s too late, and since the tangent of declination = 1, the west end of the declination axis was elevated 1′ in the first position and depressed 1′ in the second. If the star had had any other declination, as δ, the 4^s should have been divided by the tangent δ before it was converted into an arc. There is a second astronomical method which may perhaps suit some observers better, though less satisfactory, as it depends entirely on the accuracy of the position of the polar axis in azimuth. Having clamped the hour-circle very firmly when the instrument is nearly in the meridian, observe the transits of some stars near the equinoctial and others distant from it. If the distant stars agree in giving the same clock error with the stars near the equinoctial, the declination axis is rightly placed in respect of inclination; but if not, then, taking the clock errors from the equatorial stars, it will readily be seen whether the stars between the pole and the equator pass too early or too late. If they pass too early, the west end is high, if too late, the east end is high, and the inclination of the axis in arc is equal to $15'' \times \dfrac{\textit{error in time}}{\textit{tan.}\ \delta}$. In both these astronomical modes no error of collimation is supposed to exist.

The mechanical adjustment varies a little according as the level is applied. [LEVEL.] This may rest with its Ys upon the pivots of the declination axis, as in the altitude and azimuth circle [CIRCLE] and transit [TRANSIT], or hang from two cylinders, which, being fixed on the declination axis and parallel to it, project so far as to allow a level suspended from them to swing clear of the axis in all positions of the telescope. Place the declination axis horizontal by the level, and read the hour-circle; turn the polar axis half round, and place the declination axis horizontal again, and again read the hour-circle. If the readings are the same (or where the graduation is to 24^h, differ exactly 12^h) in both positions, the declination axis is adjusted; but if not, place the hour-circle half way between the positions it actually has and that which it ought to have, and make the declination axis horizontal by raising or depressing the screws which adjust it. The swing level requires a preliminary adjustment, that of making the cylinders from which it hangs parallel to the declination axis, which is to be performed thus: By turning round the telescope, bring the level directly below the declination axis; and by turning round the polar axis, bring the bubble into the middle, and clamp the hour-circle. Turn the telescope half round, when the level will be directly above the declination axis. Then, if the bubble run towards one end, bring it half way back by the screws which raise one of its supports, and the other half by the tangent screw of the hour-circle. The process must be repeated till it is satisfactory. The level itself is to be adjusted, as all levels are, by reversing it end for end on its cylinders.

6th. The instrument having been placed in the meridian, and clamped there, the hour-circle verniers, or microscopes, are to be set to mark 0^h. If the observer have the means of getting his time with tolerable accuracy, he may perfect his adjustment thus: Clamp the instrument approximately in the meridian, observe the transit of one or more known stars not far from the equator, and correct the time of observation for the known error of the clock. Then, as the right ascension of the star = true sidereal time of observation ± true hour angle from the meridian, the true hour angle is known, and the verniers, or microscopes, may be set to mark it. Or the declination axis may be set horizontal by the level, when, if the previous adjustments have been properly performed, the instrument is in the meridian, and the verniers or microscopes set to mark 0^h.

By attending to these rules and repeating the operation (stars near the pole may be safely used the second time), the instrument will be found to be very nearly in adjustment, and it is desirable that it should be so. The computation of instrumental corrections is tedious and perplexing, and most ordinary observers would blunder in the attempt; after all, the results of an equatorial, used as an *independent* instrument, are little to be relied upon. Except for observations of N.P.D. near the meridian, in reversed positions of the polar axis, as described in the first and second adjustment, the best equatorial must always be inferior to an indifferent vertical circle. Out of the meridian the careful observer will always use it as a differential instrument, which is its peculiar destination.

In the rules above given it will be remarked that the observer is directed, in every case but the 3rd, to place the instrument nearly in the meridian. This is the most favourable position of the instrument in its ordinary construction as regards symmetry and strength. Besides this advantage, the computation for refraction in or near the meridian is very simple, being the same in N.P.D. as in zenith distance,[*] while it is 0 in R.A. For the third adjustment, the formula of computation, where great accuracy is not required, is refraction = 57″.7 × tang. N.P.D. of star, or the ordinary formula for refraction in altitude, using the star's polar distance instead of its zenith distance. The formula is more accurate the nearer the star is to the pole, but in these latitudes will be sufficiently correct if the N.P.D. do not exceed 60°. An adjustment within 10″ may be considered to be close enough for all practical purposes.

The equatorial, being thus adjusted, is ready for use, and may be turned upon any star at pleasure. Suppose it be required, at sidereal time $13^h\ 14^m$, to find a star, the R.A. of which is $17^h\ 33^m$, N.P.D. 67° 28′. As the R.A. of the star is greater than the sidereal time, the star has not yet come to the meridian, or the hour angle is east. Subtracting $13^h\ 14^m$ from $17^h\ 33^m$, we have $4^h\ 19^m$ for the east hour angle. Turn the telescope to the east, and set to the reading $12^h - 4^h\ 19^m$, or $7^h\ 41^m$ of the hour-circle;[†] then set the declination circle to 67° 28′ N.P.D., and the star will be nearly in the centre of the field. With a little practice an observer can make an approximate allowance for refraction by taking away a few seconds from the hour-angle, and a minute or two from the N.P.D. If the star be very near the horizon, the usual course is to put on a low power to the telescope, and, having thus found the star, to set the telescope exactly upon it, and then to apply the power best adapted to the observation in view. The telescope being clamped in N.P.D. will follow any star by moving the instrument round in R.A. with an angular velocity equal to the apparent motion of the heavens. This motion is best given by clockwork, which is now pretty generally in use; and, indeed, for the measurement of double stars, the observation of occultations, eclipses of Jupiter's satellites, and all optical and micrometrical purposes, is nearly indispensable.

It is not necessary actually to correct each adjustment before proceeding to the next, and the errors in R.A. may be determined at the same time with those in N.P.D. by any person who understands the mysteries of a simple equation and the *law* of the errors. As the subject has not, we believe, been treated very satisfactorily, at least in any English publication, we shall proceed to deduce the errors and corrections of an equatorial every way out of adjustment from observations. We take as an example July 8, 1836.

Star.	Face of Dec. Circle.	Sidereal Time.	Observed Hour-Circle.	Observed N.P. Distance.
		h. m. s.	h. m. s.	° ′ ″
β Urs. Min. . .	E.	14 53 14·5	0 2 56·6	15 15 15
Ditto	W.	15 4 53·8	0 14 16 8	15 8 55
α Urs. Maj. . .	W.	17 1 8 0	6 8 45·8	27 16 52
δ Aquilæ . . .	W.	19 18 11·8	0 2 15·2	87 11 21
Ditto	E.	19 29 41·3	0 13 48·4	87 17 36

The sidereal time is corrected for the error of the clock, and the mean readings of the hour-circle and declination circle are corrected for refraction.

The instrumental N.P. distances, instrument east, are larger than those, instrument west, and the difference is

for β Ursæ Minoris .	6′ 20
for δ Aquilæ. . . .	6 15
Mean . . .	6 17·5=double index error.

or the index error is 3′ 8·7″ to be *subtracted* inst. E., and *added* inst. W.

Again taking the mean of the N.P.D. inst. E. and W.

	Inst¹. N.P.D.	N.A. Alm.	Differ.
	° ′ ″	° ′ ″	′ ″
β Ursæ Minoris .	15 12 5·0	15 10 17	1 48

and as the instrumental exceeds the true N.P.D. and both stars are above pole, it follows that the pole of the instrument is *below* the pole of the heavens.

α Ursæ Majoris is nearly in the 6 hour meridian west, and therefore in a proper position for determining the azimuthal deviation of the pole: we shall suppose it is exactly at 6 hours from the meridian.

---

[*] The refraction in N.P.D. may be taken from any of the tables, as the zenith distance is equal to the N.P.D. of the star, after subtracting the co-latitude for the upper culmination and adding it for the lower. The correction is to be added to the instrumental N.P.D., when the star is south of the zenith or *sub polo*, and to be subtracted when the star is between the pole and the zenith.

[†] The hour angle reckoned from the meridian is always the difference between the sidereal time and the R.A. of the star. When the sidereal time is less than the R.A. of the star, add 12h to the sidereal time, and then, after subtracting the R.A. of the star, you have the reading of the hour-circle, according to the graduation into two twelves. If the graduation is from 0h to 24h, add 24h instead of 12h to the sidereal time, and subtract the R.A. as before.

Correcting for the index error, we have 27° 16′ 52″ + 3′ 9″ = 27° 20′ 1″, for the instrumental N.P.D., whereas the Nautical Almanac gives the true N.P.D. of this star = 27° 21′ 42″. The difference is 1′ 41″, which is the quantity by which the pole of the instrument is to the west of the pole of the heavens. We have therefore determined the error of the polar axis and the index error of the declination circle, which may be corrected, if necessary, by altering the screws.

δ Aquilæ is very near the equator, and therefore proper for determining the error of collimation in R.A. The sidereal time between the observations is $11^{m}\ 29^{s}{\cdot}5$, and the difference between the readings of the hour circle is $11^{m}\ 33^{s}{\cdot}2$, hence the error of collimation in the equator is $\frac{3^{s}{\cdot}7}{2}$ or $1^{s}{\cdot}85$, which is to be added to the hour angle of the observation, Inst. W., and subtracted, Inst. E. For stars out of the equator this correction is to be multiplied by the secant of declination. Now the secant of declination for β Ursæ Minoris = 3.82, hence the effect of collimation for this star = $3{\cdot}82 \times 1^{s}{\cdot}85 = 7^{s}{\cdot}1$ nearly, and subtracting this from the hour angle of the first or E. observation, and adding it to the second or W. observation, we have E. $0^{h}\ 2^{m}\ 49^{s}{\cdot}5$ and W. $0^{h}\ 14^{m}\ 23^{s}{\cdot}9$ for the hour-circle readings corrected on account of collimation. The difference between these is $11^{m}\ 34^{s}.4$, while the sidereal time elapsed is $11^{m}\ 39^{s}{\cdot}3$, and half the discordance between these two results $\frac{4^{s}{\cdot}9}{2}$ or $2^{s}{\cdot}45$ is the error due to the inclination of the declination axis. As this error varies as the tangent of declination, which in β Ursæ Minoris = 3·69, the error for any other star = $\frac{2{\cdot}45}{3{\cdot}69} \times \tan.\ \delta = 0^{s}{\cdot}7 \times \tan\ \delta$ nearly. It is evident that this correction is to be subtracted from the instrumental hour angle, Inst. E., and to be added, Inst. West. The sign is to be changed if the correction is to be applied to the sidereal time of the observation, that is, if the observer wishes to adjust his instrument (when it is E., for instance), he must make the time of passage later than it is, which is done by lowering the west end of the declination axis. In this case the quantity is $0^{s}{\cdot}7$ or $10''{\cdot}5$.

No considerable error arises from omitting the effect of inclination upon δ Aquilæ in the above example; but it is more satisfactory to deduce both the coefficients of collimation and inclination at once.

Let c be the constant of the correction for the collimation and i for the inclination, both + when Inst. W. and when the correction is to be applied to the hour angle; then substituting the numerical values of the secants and tangents of the two stars, we shall have for the corrected hour angles.

$$\begin{array}{lllll}
 & & \text{h} & \text{m} & \text{s} \\
\beta\ \text{Ursæ Minoris} & \text{E.} & 0 & 2 & 56{\cdot}6 - 3{\cdot}82c - 3{\cdot}69i \\
\quad ,, & \text{W.} & 0 & 14 & 16{\cdot}8 + 3{\cdot}82c + 3\ 69i \\
\hline
\text{Difference}\ .\ .\ . & & & 11 & 20{\cdot}2 + 7{\cdot}64c + 7{\cdot}38i = 11\quad 39^{s}{\cdot}3. \\
\delta\ \text{Aquilæ,} & \text{W.} & 0^{h} & 2^{m} & 15^{s}{\cdot}2 + 1{\cdot}00c + 0{\cdot}05i \\
 & \text{E.} & 0 & 13 & 48{\cdot}4 - 1{\cdot}00c - 0{\cdot}05i \\
\hline
\text{Difference}\ .\ . & & 0 & 11 & 33{\cdot}2 - 2{\cdot}00c - 0{\cdot}10i = 11^{h}\ 29^{m}{\cdot}5,
\end{array}$$

which give for the determination of c and i

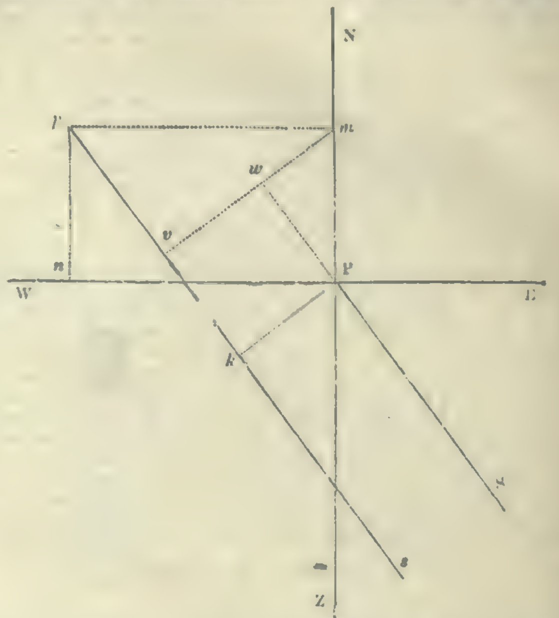
$$7{\cdot}64c + 7{\cdot}38i = 19{\cdot}1$$
$$2{\cdot}00c + 0{\cdot}10i = \ 3{\cdot}7$$

from which i is found = 0·71 c = 1·81 nearly as before.

In this way, by forming an equation for each star, and combining all the observations in which i has a small coefficient into one equation (when stars have south declination, or are *sub polo*, the coefficient is negative), and those where the coefficient of i is large into another, the value of i and consequently of c, may be determined with great accuracy. It is not absolutely necessary that the observations for deducing these corrections should be near the meridian, but it is desirable that as little time as possible should elapse between each of the pair of observations, on account of the variation of refraction and of the effect of polar error, if that be considerable. As a general rule, it would be well to keep within a few minutes of the meridian, for in the above example the variation of refraction in β Ursæ Minoris is $0^{s}{\cdot}5$, while the variation of the effect of polar error is no less than $1^{s}{\cdot}3$. Besides, the instrument is always most perfect near the meridian, and is to be used there when possible.

If the errors be corrected by adjustment, the index error of the hour-circle is simply the difference between the observed hour angle and the true hour angle. Or supposing the true sidereal time unknown, the index error must be determined by a level, as we have described above, after placing the declination axis horizontal. But if instead of actually adjusting the instrument, the errors are noted and corrections applied, we have yet to compute the effect of polar deviation upon the observations in R. A. before the index error can be correctly obtained. In order to do this, we must consider the polar deviation more minutely; and as we have reason to think that from a want of skill in detecting the polar error of an equatorial, or in applying the corrections which depend upon this error to observations, especially in R. A., observers have been led to impeach too hastily the character of instruments, we shall explain this part of the subject very fully.

Let P be the place of the pole of the heavens, and p that of the pole of the instrument when prolonged indefinitely, as seen on the sphere of the heavens by a spectator outside; N P Z the meridian of the place, which, when produced towards Z, passes through the zenith and the south point of the horizon; E P W the 6-hour meridian, which passes through the east and west points of the horizon. Let fall $p\,m$ and $p\,n$ perpendicular on Z N and E W, and let $p\,m$ or P n = x'' and $p\,n$ or P m = y''. It is presumed that the index error of the declination circle has been obtained by reversed observations, which is indeed the universal rule, and therefore that the observed N.P. distances, corrected for index error and refraction, express the actual distances of the stars from p.



Let a tolerably distant star be observed, the place of which is in the direction of $p\,s$ when continued; draw P k perpendicular to $p\,s$, and also P S from the true pole towards the star, hence Z P S is the true hour angle of the star.

Then, since the instrument is nearly in adjustment and the star not very near the pole, P S and $p\,s$ are nearly parallel, and P k is perpendicular to both, hence the distances of the star from P and k are equal, and the effect of polar error on the N.P.D. of the star is to make its instrumental polar distance too large by $p\,k$. Drawing $m\,v$ perpendicular, and P w parallel to $p\,s$,

$$p\,k = p\,v + v\,k \text{ or P}w$$
$$= p\,m \times \cos.\ m\,p\,v + \text{P}m \times \cos.\ m\,\text{P}\,w;$$

or, since $m\,p\,v$ is the complement of $n\,p\,v$, which is = Z P S, and m P w = Z P S,

$$p\,k = x'' \times \sin.\ \text{east hour angle} + y'' \times \cos.\ \text{east hour angle}.$$

From this formula, if x and y be known in quantity and direction by observations in the meridian and at six hours from it, the value of $p\,k$ may be computed and applied as a correction to the observed N.P.D. of any star, and the observed hour angle will serve for the computation.

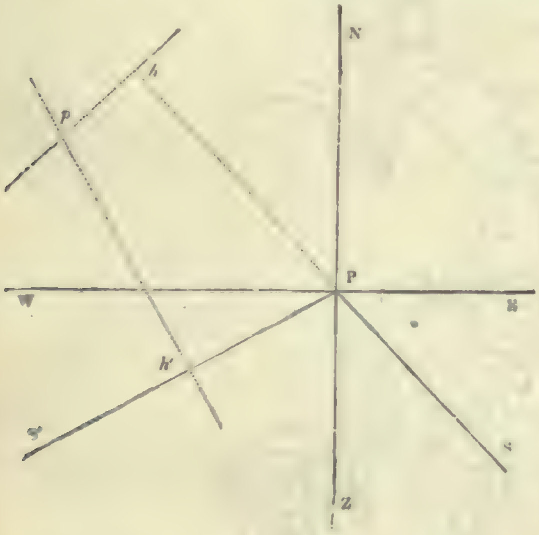
In practice we have found it sufficiently accurate to draw $p\,n$ P on a scale where seconds are visible,—that is, equal to about $\frac{1}{50}$ inch,—and then making the angle $n\,p\,s$ equal to the observed hour angle, and letting fall P k perpendicular on $p\,s$ to ascertain the value of $p\,k$ by compass and scale. It is not possible to commit an error of more than 2″ or 3″, which is generally of little importance; and besides the superior rapidity of the operation, there is no danger of confounding the *sign* of either part of the correction, whether the star be above or below pole, which even careful and experienced computers can scarcely at times avoid. In any case the graphical process will afford a very useful check.

The effect of the displacement of the polar axis upon the readings of the hour circle may easily be gathered from the same figure. Suppose the two lines P S and $p\,s$ to be continued till they meet at the star, and to be produced, if necessary, until they cut the equator in Σ and σ. The reader may imagine or draw the figure. If the star be north of the equinoctial, the lines P S Σ and $p\,s\,\sigma$ cross at the star, and the hour angle corresponding to p is to the east, and greater than the hour angle corresponding to the true pole P. Hence the reading of the hour circle is too small in the case represented in the figure, or Σσ is to be added to the reading of the hour circle. Also, since σ Σ : Pk : : sin. δ : cos. δ ∴ σ Σ = Pk × tan. δ. Again,

$$\text{P}k = mv - mw$$
$$= pm \times \sin.\ mpv - \text{P}m \times \sin.\ m\text{P}w$$
$$= x'' \times \cos.\ \text{east hour angle} - y'' \times \sin.\ \text{east hour angle}.$$

The reader will have no difficulty in following out the rules with regard to the signs of the correction in each particular case, but it will be much safer and quite accurate enough to take the value of P*k* from the figure and to multiply it by $\frac{1}{15}$ tan. δ for the correction. As a practical direction we have found this convenient. Join P*p*, and produce it both ways. Then according to this figure, the correction is additive to the hour circle reading for all stars having north declination which are observed on the south side of P*p* produced, and *vice versâ* for stars on the north side. The tangent of declination is negative when the star is south of the equinoctial, and the rule is reversed. There is no correction for stars in the direction of P*p*, that is for stars having an east hour angle from the south or a west hour angle from the north, such that its tangent $= \frac{x}{y}$. After this correction has been applied, the index error of the hour circle may be deduced in the manner pointed out.

It sometimes happens that an observer, from carelessness or want of time or knowledge, does not determine the position of the pole of the instrument by the best means, viz., by observations in the meridian and at six hours from it, but that this position is to be deduced from a higgledy piggledy mass of observations made in different parts of the heavens. To form equations such as we have just given for each observation, and to solve them by the method of minimum squares, might possibly be the most accurate mode; but the labour would be very great, and on such an object very much misspent. We have found the graphical process quite sufficient, and it has the further advantage of exhibiting to the eye those observations which, from their extravagance, are probably errors in bisecting the star or in reading off the verniers. Suppose such a set of observations to be given for reduction. Draw W E and N Z, at right angles to each other, and intersecting at P, and then draw from P lines such as PS, PS′ for each known star observed, making the angles SPZ, S′PZ equal to the observed hour angles of the stars. If the instrumental polar distance be less than that of the catalogue, as in S′, take P*h*′ = the difference; if the instrumental distance be greater, as in S, prolong SP and take P*h* = the difference. Through *h* and *h*′ draw perpendiculars to PS and PS′, and these will intersect at *p*, the place of the instrumental pole. Repeating this process for each known star, the eye will show pretty nearly where *p* should be chosen among the various intersections. The place of *p* being determined, the observations of an unknown star or comet may be corrected as shown above; and by dropping perpendiculars on PW and PN, the azimuthal and vertical errors of the pole of the instrument may be determined.



It seems scarcely necessary to caution any person into whose hands such observations may come, against relying upon intersections which are made at very acute or very obtuse angles. If, for instance, we were to attempt to deduce the place of *p* as to azimuth by a pair of observations near the meridian, or its place as to altitude by observations near the 6 hour meridian, we should only have our own folly to blame for the inaccuracy of the result. From the nature of the case, the unavoidable errors of observation would be multiplied by the process, and a result of any kind might be obtained, just as by observing the sun near noon for time and near the prime vertical for latitude, a sailor might cause his sextant to be guilty of any assignable error. This is evident from the form of the analytical equation, but any non-algebraist may satisfy himself by drawing lines PS and PS′, making an angle of 5° or 10°, and by finding what the effect of an error of 10″ in the observations will be on the position of *p*. If three observations of stars without reversion should be employed, and the index error of the declination circle be deduced at the same time, the blunder will be complete.

Though the errors of an unadjusted equatorial may be detected and the corrections rigorously computed, it would be an abuse of time and calculation to do so. In two of the ordinary constructions of the instrument and probably in the third, the instrumental errors are not and cannot be expected to be accurately the same in all positions of the instrument. In those equatorials of Ramsden's construction which have five feet telescopes and declination circles of three feet diameter, variations of adjustment between the meridian and six hours from it may be expected to amount to 10″ or 20″, and in the largest equatorials, which are necessarily more imperfect, discrepancies of 1′ or even 2′ may arise. We shall now point out the rational mode of using an equatorial instrument, when the object is to determine the place of any phenomenon in the heavens.

The first thing is to adjust the instrument with great care, and especially to make the pole of the instrument agree with the celestial pole. The permanence of this adjustment depends solely upon the steadiness of the upper and lower supports, which should therefore be fixed very solidly. This being done, suppose a comet is to be determined. Turn the telescope upon it, and having clamped the hour circle very firmly, note the transit of the comet over the vertical wires, bisecting it at the same time in N.P.D. by the horizontal wire. Wait till some other star passes over the field, note its transit, and bisect it in N.P.D. by moving the micrometer screw only. In this case the declination circle is supposed to be firmly clamped between the observations. Then the difference of the times of observation gives the difference of R.A. between the comet and star, and the difference in declination is taken from the micrometer. It is the same thing, of course, whether the star precedes or succeeds the comet. Observations of this kind are amongst the most perfect which can be made, for the errors of the instrument being the same in each case, and the refraction almost the same, no error can creep in except that of noting the phenomenon. The star which is sometimes called the *determining star*, or the *star of comparison*, is afterwards observed by meridian instruments, and then the place of the comet is deduced with the greatest accuracy. Frequently, however, there is a dearth of stars of comparison, and the time before a proper star enters the field is too long for the patience of the observer, or he may not have a micrometer. In this case the instrument is kept clamped in R.A., and after observing the comet, the telescope is moved up or down a little, and stars above and below the comet are observed, in R.A. by noting the clock, and in declination by reading the circle. The instrument should then be turned half round in R.A., and the operation repeated. By combining both sets, as good a place of the comet will be deduced as the division of the declination circle will allow. The stars of comparison are taken above and below, so that the mean of the instrumental errors at the stars may be pretty nearly equal to that at the comet, and as the effect in R.A. of an error of collimation or inclination is changed in sign by reversion, it is therefore eliminated from the mean. The instrument must on no account be moved in R.A. between the observation of the comet and the stars of comparison. In this way Halley's comet was observed at Greenwich and Cambridge, the stars of comparison were subsequently observed with the meridan instruments, and the apparent places of the comet finally settled. The details will be found in the observations of the respective observatories for the year 1835.

If the utmost accuracy be not required, it is sufficient, after careful adjustment, to note the transit of the comet over the vertical wires, and to read off the declination and hour circle, and then turning the instrument upon one or more neighbouring stars, to observe them in like manner. The nearer the stars of comparison are to the comet, the greater probability there is that there is no change, or only a slight change of instrumental error in moving from one to the other. This mode of observation, however, is only to be tolerated in cases of necessity, when, either from haste or uncertain weather, the observer cannot wait for stars coming to the same meridian with the comet.

Suppose the following observations to have been made of *Arcturus* and of an unknown star or comet, after correcting each for refraction.

	Time by Clock.	Hour Circle.	North Polar Dist.
	h. m. s.	h. m. s.	° ′ ″
Arcturus	17 17 9·9	3 10 15·5	69 54 46
Comet	17 27 11·5	2 50 38·1	62 11 1

To determine the index errors of both circles by Arcturus, we have

	h. m. s.		° ′ ″
Time by clock	17 17 9·9	Instruml. N.P.D .	69 54 46
Hour angle west	3 10 15·5	Ditto Naut. Alm. .	69 57 37
Instrumenl. R.A.	14 6 54·4	Instruml. N.P.D. *too small*	2 51
R.A. Naut. Alm.	14 8 10·6		
Instrumenl. R.A. *too small* .	1 16·2		

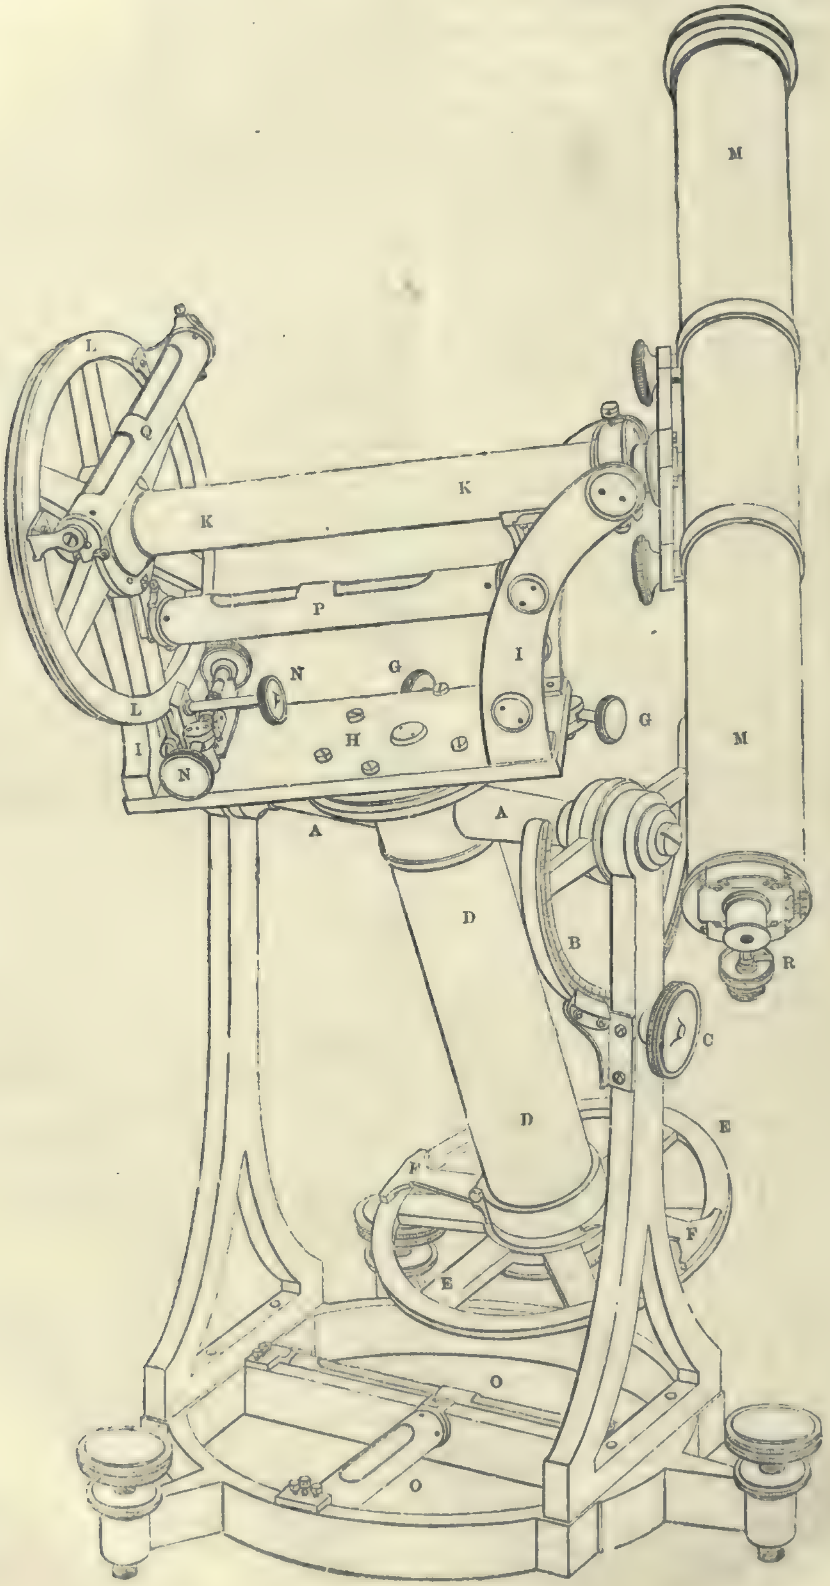
Applying these corrections to the observations of the comet, we have

	h.	m.	s.
Time by clock	17	27	11·5
Instl. hour angle	2	50	38·1
Instl. R.A. comet	14	36	33·4
Correction . .	+ 1		16·2
True R.A. comet	14	37	49·6

	°	′	″
Instrumentl. N.P.D.	+ 62	11	1
Correction	+	2	51
N.P.D. . .	+ 02	13	52

The star of comparison is, in this case, much too distant both in R.A. and N.P.D.; and the index error ought to be determined by stars above and below the comet, and preceding and succeeding it. Also, after the observations have been made in one position of the instrument, it ought to be turned half round and the observations repeated; but the mode of ascertaining and applying the corrections is the same, and needs no further explanation.

The accompanying figure represents the *portable universal equatorial* as constructed by Troughton (a drawing and description of a similar instrument, under the title of *Fayrer's Equatorial* will be found in



The Equatorial.

Rees's 'Cyclopædia,' article EQUATORIAL). The lower part or stand rests on three foot-screws, and needs no description. The upper part is moveable on a cross axis A A, on which it is balanced; and when the polar axis is set at the proper inclination by the latitude semicircle B, the clamp C retains it there. The polar axis consists of an outer tube, D D, forming one piece with the horizontal axis above-mentioned, and of an interior axis which turns freely within the tube as in a socket. This latter axis carries the hour circle, E E, the verniers, F F, being fixed to the tube. The clamp and tangent screw of the hour-circle are partially seen at G G. The upper plate H is fixed on the inner axis, and revolves with it. Two pieces, I I, rise from this plate, and carry the collars within which the cross or transit axis, K K, works. The declination circle, L L, and telescope, M M, are fixed to the extremities of the transit axis, the telescope being outside the collar. The declination clamp and tangent screw are seen at N N; the verniers are on the other side. These are attached to the support which rises from the plate H. Two levels are fixed on the lower part of the stand at O O, but they are only to be used for approximate adjustment. A delicate swing level, P, is hung from the transit axis, and a second level, Q, is fixed to the declination circle. The telescope has a micrometer, R, carrying wires for measuring small differences of declination.

It is evident to those who know Fraunhofer's construction, that it is identical with the upper part of this universal equatorial. The suspension and motion of the polar axis and hour circle are the same as in the equatorial made by Troughton for the University of Coimbra. The position of the telescope is that of Megnié and Nairne.

The rules we have already given will enable any one to adjust the universal equatorial; but if the direction of the meridian be known, it is a simpler plan to adjust the instrument as an altitude and azimuth circle, which it becomes when the polar axis is vertical, and then by inclining the polar axis to the latitude of the place, it becomes an equatorial. There is no provision in the instrument itself for moving the polar axis in azimuth. The whole must be turned bodily, and for this purpose some preparation should be made in the stand on which the foot-screws rest.

The following references will be useful to the reader. A clock for carrying an equatorial, constructed by Messrs. Troughton and Simms, is described in the 'Abstracts of the Proceedings of the Royal Astronomical Society,' vol. iii., No. 6, with a wood-cut. This would probably act somewhat more steadily with a horizontal fly-wheel upon the vertical axis, but its performance is very good. An account of the slipping piece and the wire micrometer to be applied to the equatorial for observing double stars, with directions for their use, is given in the appendix to the 'Companion to the Maps of the Stars published by the Society for the Diffusion of Useful Knowledge,' 1836. For the mode of using the equatorial as a measuring circle, see the 'Cambridge and Greenwich Observations' for 1835 and 1836 of Halley's Comet, of the Solar Eclipse, and of the elongation of Jupiter's fourth Satellite; and for the corrections for refraction and parallax, the 'Introduction to the Greenwich Observations,' 1836, to which the reader should look if he wishes to know the best methods of making and reducing astronomical observations in general. Sir George Shuckburgh's 'Memoir' already referred to contains a valuable history of the instrument, though on consulting the authorities, we have been led occasionally to differ from him. A description of Ramsden's *refraction piece* will be found at page 19 of Shuckburgh's paper, along with a collection of tables for computing the effects of refraction and parallax in R.A. and N.P.D. from the data which this ingenious appendage affords. Pearson's 'Practical Astronomy,' vol. ii. p. 517; Littrow, 'Memoirs of the Astronomical Society,' vol. ii. p. 45; Kriel, 'Mem. Ast. Society,' vol. iv. p. 495.

EQUERRIES (from the French *écurie*, a stable), the name given to certain officers of the Royal household in the department of the master of the horse, the first of whom is styled chief equerry and clerk-marshal. Their duties fall in rotation. When the sovereign rides abroad in state, an equerry attends. Officers of the same denomination form a part of the established households of the royal dukes, &c.

EQUIANGULAR, EQUILATERAL, EQUI-CRURAL, EQUI-TANGENTIAL, &c. &c., a class of words beginning with EQUI, which, in composition forms an adjective expressive of the equality of two things spoken of. Thus equiangular means having equal angles, and so on. There is a certain liability to confusion, arising from mistaking between the application of such terms to different parts of the same figure and to different figures. Thus 'an equilateral triangle' must mean a triangle which has three sides all equal. But 'two triangles which are equilateral' may mean two triangles in which every side of the first has its equal among those of the second: the two not being separately equilateral. To avoid this, it is sometimes said that two triangles, such as have just been mentioned, are *mutually* equilateral.

EQUILI'BRIUM (*æqua libra*), a state of rest produced by the mutual counteraction of two or more forces. The science of equilibrium is STATICS.

EQUIMULTIPLES, multiples in which equal numbers of times are taken. Thus *seven* times A and *seven* times B are *equi*-multiples of A and B: a league and a yard are equimultiples of a mile and a foot. The student of the fifth book of Euclid should remember that this word has no singular number: 7 A and 7 B are equimultiples, but 7 A is not therefore to be called *an* equimultiple but *one of the* equimultiples. And the same of the word equal, whether separately or in composition: A and B may be equal lines, but A is not *an equal* line. Equality implies comparison of at least two things.

EQUINOCTIAL, a name given to the equator, from the night being equal to the day when the sun is there.

EQUINOXES, the intersections of the equator and ecliptic; the vernal equinox being that in which the sun is when about to rise into the northern hemisphere; the autumnal equinox being that in which the sun is when about to sink in the southern hemisphere. These terms are relative: for the equinox which is vernal in our hemisphere is autumnal in the southern, and *vice versâ*.

EQUISE'TIC ACID, *Aconitic Acid* ($3HO, C_{12} H_3 O_9$) an acid discovered by Bracconot in the *equisetum fluviatile*, in which it exists combined with magnesia.

This acid may be obtained in small colourless radiating crystals; its taste is sharp, and somewhat analogous to that of tartaric acid: it is unalterable in the air. When heated, it decomposes without subliming, and yields an oily uncrystallisable acid product. It dissolves readily both in alcohol and in water: the solution gives no precipitate either with lime or baryta water, but with acetate of lead and protonitrate of mercury it gives white curdy precipitates: it precipitates the persalts, but not protosalts of iron.

With potash and soda it yields deliquescent uncrystallisable salts; with ammonia, a crystallisable salt. With oxide of zinc, with lime, and magnesia, it forms uncrystallisable transparent compounds, which are unalterable in the air. [ACONITIC ACID; CITRIC ACID.]

E'QUITES (horsemen), the name of an order in the Roman state. Their origin, according to the old tradition, was this:—Romulus having divided his subjects into three tribes, chose from each one hundred young men whom he destined to serve on horseback and act as his body-guard; this body of cavalry was called the *celeres*, and afterwards the *equites*. (Dionys., ii. 13.) Niebuhr supposes ('Hist. of Rome,') that whereas *patres* and *patricii* were titles of honour for individuals, *celeres* was the name of the whole class as distinguished from the rest of the nation. The three centuries of the *celeres* were called by the same names as the three tribes of the patricians, namely, Ramnes, Tities, and Luceres. Their tribunes are spoken of as a college of priests (Dionys., ii. 64), and it appears that the tribes of the patricians had also tribunes (Dionys., ii. 7). Moreover, when it is said that Tarquinius Priscus made three new centuries, which he added to the former three, and that the whole went under the name of the Sex Suffragia, or the six equestrian centuries, we cannot doubt that the alteration which he introduced was a constitutional and not merely a military one; that in fact the centuries which he formed were, like the original three, tribes of houses; that his innovation was nothing but an extension of the political division of the inhabitants of Rome under Romulus. (Niebuhr, "Hist. of Rome.") When Servius Tullius established the comitia of the centuries, he received the sex suffragia, which included all the patricians, into his first class; and to them he added twelve other equestrian centuries, made up of the richest of the plebeian order. (Niebuhr.) The ancient writers appear to have laboured under some great confusion with regard to this arrangement. Livy (i. 43) makes a proper distinction between the twelve equestrian centuries created by Servius and the six which existed before; but when he states (i. 36) that the cavalry in the reign of Tarquinius Priscus amounted to 1800, he appears to be antedating the origin of the eighteen equestrian centuries which formed part of the constitution of Servius. To the establishment of the comitia centuriata the creation of a body of equites, as a distinct order, seems to be due. The plan of Servius was, to a certain extent, identical with that of Solon. The object of both legislators was to break down the limits to which the old aristocracy was confined, and to set up an order of wealth by the side of the order of birth: not, however, that when a person could produce his 400,000 sesterces, he became *ipso facto* a knight, as was the case in after times. (Hor. "Ep." i. 1, 57.) According to the Servian constitution, good birth or the sanction of the censors was necessary for gaining a place in the equestrian order. (Polyb., vi. 20; Zonaras, vii. 19.) When Cicero says ("De Republica," ii. 20) that Tarquinius established the equestrian order on the same footing as that on which it stood in his own time, and also attributes to the same king the assigning of money to the equites for the purchase and keep of their horses, he is evidently inconsistent. In Tarquin's time, that is, before there was any plebeian order, it was natural enough that the poorer patricians, who were obliged to serve on horseback, just as the 'Ιππῆς at Athens, who were a poorer class than the Pentakosiomedimnoi, (Plut., "Sol." c. 18.) should be furnished with the means for doing so. But the case was different with the equites after the establishment of an order of wealth. A man might then be of equestrian rank, and yet have no horse assigned to him; thus, on the one hand, we find at the time of the siege of Veii a number of equites serving on horseback at their own expense (Liv., v. 7); and, on the contrary, L. Tarquitius, who was a patrician, was obliged to serve on foot from his poverty. (Liv., iii. 27.) From this it appears probable that a certain sum was fixed which it was not necessary for every eques to have, but the possessor of which was obliged to serve on horseback at his own expense if no horse could be given him by the public, and that those whose fortune fell short of this were obliged to serve in the infantry under the same circumstances.

The lieutenant of the dictator was called "the chief of the equites" (*Magister Equitum*); and although in later times he was appointed to this office by the dictator himself, it is probable, as Niebuhr conjectures (i., p. 559), that he was originally elected by the twelve centuries of Plebeian equites just as the dictator, or *Magister Populi*, was by the *Sex Suffragia*, in other words, by the Populus or Patricians.

With regard to the functions of the equites, besides their military duties, they had to act as judices or jurymen under the Sempronian law: under the Servilian law the judices were chosen from the senate as well as from the equites: by the Glaucian law the equites alone performed the office, and so on by alternate changes till the law of Aurelius Cotta (B.C. 70), by which the judices were chosen from the senators, equites, and tribuni ærarii. The equites also farmed the public revenues. Those who were engaged in this business were called the *Publicani*; and though Cicero, who was himself of the equestrian order, speaks of these farmers as "the flower of the Roman equites, the ornament of the state, the safeguard of the republic" ('Pro Plancio,' 9), it appears that they were a set of detestable oppressors, who made themselves odious in all the provinces by their avarice and rapacity.

The equites, as it may be inferred from what has been already said, gradually lost the marks of their distinctive origin, and became, as they were in the time of Cicero for instance, an ordo or class of persons as distinguished from the senate and the plebs. They had particular seats assigned to them in the circus and the theatre. The insignia of their rank, in addition to the horse, were, a golden ring and the angustus clavus, or narrow band, on their dress, as distinguished from the latus clavus or broad band of the senators: the two last insignia seem to have remained after the former ceased to possess its original and distinctive character.

EQUITY, according to the definition given by Aristotle, is "the rectification of the law, when, by reason of its universality, it is deficient; for this is the reason that all things are not determined by law, because it is impossible that a law should be enacted concerning some things; so that there is need of a decree or decision; for of the indefinite the rule also is indefinite: as among Lesbian builders the rule is leaden, for the rule is altered to suit the figure of the stone, and is not fixed, and so is a decree or decision to suit the circumstances." (*Ethics*, b. v. c. x. Oxford trans.) "Equity," says Blackstone, "in its true and genuine meaning, is the soul and spirit of all law; positive law is construed and rational law is made by it. In this respect, equity is synonymous with justice; in that, to the true and sound interpretation of the rule." According to Grotius, equity is the correction of that wherein the law, by reason of its generality, is deficient.

Until jurisprudence has become really a science based on settled principles, some such jurisdiction as our earlier law writers have attributed to the courts of equity is necessary to the due administration of justice; and it is probable that in England it deserved the humorous description given by Selden in his 'Table Talk:' "Equity in law is the same that spirit is in religion, what every one pleases to make it; sometimes they go according to conscience, sometimes according to law, sometimes according to the rule of court. Equity is a roguish thing; for law we have a measure, know what to trust to; equity is according to the conscience of him that is chancellor, and as that is larger or narrower, so is equity. It is all one as if they should make the standard for the measure we call a foot a chancellor's foot; what an uncertain measure would this be! One chancellor has a long foot, another a short foot, a third an indifferent foot: it is the same thing in the chancellor's conscience."

This uncertainty has however long ceased in that branch of our law which is expressed by the term Equity, and, from successive decisions, rules as strict and principles as fixed have been framed and established in our courts of equity as in our courts of law. New cases, it is true, may and do arise, but they are decided upon these ascertained rules and principles, and not from the notions of the judge as to what may be reasonable or just in the particular case before him. Nothing in fact is more common than to hear the chancellor say, that whatever may be his own opinion, he is bound by the authorities, that is, by the decisions of his predecessors in office and those of the other judges in equity; that he will not shake any settled rule concerning property, &c., it being for the common good that these should be certain and known, however ill-founded the first resolution may have been.

In its enlarged sense, equity answers precisely to the definition of justice, or natural law (as it is called), as given in the 'Pandects' (lib. i. tit. 1, l, 10, 11); and it is remarkable that subsequent writers on this so-called natural law, and also the authors of modern treatises on the doctrine of equity, as administered in the English courts, have, with scarcely any exception, cited the above passage from Aristotle as a definition of equity in our peculiar sense of a separate jurisdiction. But according to this general definition every court is a court of equity, of which a familiar instance occurs in the construction of statutes, which the judges of the courts of common law constantly interpret according to the spirit, or, as it is called, the equity, not the strict letter.

It is hardly possible to define equity as now administered in this country, or to make it intelligible otherwise than by a minute enumeration of the matters cognisable in the courts in which it is administered in its restrained and qualified sense. "It is no longer," says Sir James Mackintosh in his life of Sir Thomas More, "in the acceptation in which the word is used in English jurisprudence, to be confounded with that moral equity which generally corrects the unjust operation of law, and with which it seems to have been synonymous in the days of Selden and Bacon. It is a part of laws formed from usages and determinations which sometimes differ from what is called common law in its subjects, but chiefly varies from it in its mode of proof, of trial, and of relief."

In this country the remedies for the redress of wrongs and for the enforcement of rights are distinguished into two classes, *those which are administered in courts of law*, and *those which are administered in courts of equity*; the former are called legal rights and wrongs, the latter equitable. Equity jurisdiction may therefore properly be defined as that portion of remedial justice which is administered by a court of equity as distinguished from a court of law, from which a court of equity differs mainly in the subject matters of which it takes cognizance and in its mode of procedure and remedies.

Courts of common law in this country proceed by certain prescribed forms of action alone, and give relief only according to the particular exigency of such actions, by a general and unqualified judgment for the plaintiff or the defendant. There are many cases, however, in which a simple judgment for either party, without qualifications or conditions, or peculiar arrangements, will not do entire justice. Some modifications of the rights of both parties may be required; some restraints on one side, or the other, or perhaps on both; some qualifications or conditions present or future, temporary or permanent, to be annexed to the exercise of rights, or the redress of injuries. To accomplish such objects the courts of law in this country have no machinery: according to their present constitution they can only adjudicate by a simple judgment between the parties. Such prescribed forms of actions are not confined to our own system of laws; they were known in the civil law, and the party could apply them only to their original purposes. In other cases he had a special remedy. Courts of equity, however, are not so restrained; they adjudicate by decree pronounced upon a statement of his case by the plaintiff, and the answer of the defendant given in upon *oath*, and the evidence of witnesses, together, if necessary, with the evidence of all parties, also given upon oath. These decrees are so adjusted as to meet all the exigencies of the particular case, and they vary, qualify, restrain, and model the remedy so as to suit it to mutual and adverse claims, and the real and substantial rights of all the parties so far as such rights are acknowledged by the established rules of equity.

The courts of equity bring before them *all* the parties interested in the subject matter of the suit, and adjust the rights of all however numerous; whereas courts of law in this country are compelled by their constitution to limit their inquiry to the litigating parties, although other persons may be interested: that is, they give a complete remedy in damages or otherwise for the particular wrong in question as between the parties to the action, though such remedy is obviously in many cases an incomplete adjudication upon the general rights of the parties to the action, and fails altgether as to other persons, not parties to the action, who yet may be interested in the result or in the subject matter in dispute.

Perhaps the most general as well as the most precise description of a court of equity is the outline given by Mr. Justice Story in the 'Encyclopædia Americana,' which he afterwards filled up in his Treatise on Equity. It is this—that a court of equity has jurisdiction in cases where a plain, adequate, and complete remedy cannot be had in the common law courts. The remedy must be *plain*, for if it be doubtful and obscure at law, equity will assert a jurisdiction. It must be *adequate*, for if at law it fall short of what the party is entititled to, that founds a jurisdiction in equity; and it must be *complete*, that is, it must attain the full end and justice of the case, it must reach the whole mischief and secure the whole right of the party present and future, otherwise equity will interpose and give relief. The jurisdiction of a court of equity is sometimes concurrent with the jurisdiction of the courts of law; sometimes assistant to it; and sometimes exclusive. It exercises concurrent jurisdiction in cases where the rights are purely of a legal nature, but where other and more efficient aid is required than a court of law can afford. In some of these cases courts of law formerly refused all redress, but now will grant it. For strict law comprehending established rules, and the jurisdiction of equity being called into action when the purposes of justice rendered an exception to those rules necessary, successive exceptions on the same grounds became the foundation of a general principle, and could no longer be considered as a singular interposition. Thus law and equity are in continual progression, and the former is constantly gaining ground upon the latter. Every new and extraordinary interposition is by length of time converted into an old rule; a great part of what is now strict law was formerly considered as equity, and the equitable decisions of this age will unavoidably be ranked under the strict law of the next. (Prof. Millar's 'View of the English Government.') But the jurisdiction having been once justly acquired at a time when there was no such redress at law, it is not now relinquished by the courts of equity.

The most common exercise of the concurrent jurisdiction is in cases of account, accident, dower, fraud, mistake, partnership, and partition. In many cases which fall under these heads, and especially in some cases of fraud, mistake, and accident, courts of law cannot and do not afford any redress: in others they do, but not in so complete a manner as a court of equity.

A court of equity is also assistant to the jurisdiction of the courts of law in cases where the latter have no like authority. It will remove legal impediments to the fair decision of a question depending at law, as by restraining a party from improperly setting up, at a trial, some title or claim which would prevent the fair decision of the question in dispute; by compelling him to discover, upon his own oath, facts which are material to the right of the other party, but which a court of law cannot compel him to disclose; by perpetuating, that is, by taking and keeping in its custody, the testimony of witnesses, which is in danger of being lost before the matter can be tried; and by providing for the safety of property in dispute pending litigation. It will also counteract and control fraudulent judgments, by restraining the parties from insisting upon them.

The exclusive jurisdiction of a court of equity is chiefly exercised in cases of merely equitable rights, that is, such rights as are not recognised in courts of law. Most cases of trust and confidence fall under this head. This exclusive jurisdiction is exercised in granting injunctions to prevent waste or irreparable injury; to secure a settled right, or to prevent vexatious litigation; in appointing receivers of property which is in danger of being misapplied; in compelling the surrender of securities improperly obtained; in preventing a party from leaving the country in order to avoid a suit; in restraining any undue exercise of a legal right; in enforcing specific performance of contracts; in supplying the defective execution of instruments, and reforming, that is, correcting and altering them according to the real intention of the parties, when such intention can be satisfactorily proved; and in granting relief in cases where deeds and securities have been lost.

Much discussion has taken place and various opinions have been expressed upon the question whether it would or would not be best to administer the whole of remedial justice in one court or in one class of courts without any separation or distinction of suits, or of the forms or modes of procedure and relief. Lord Bacon, upon more than one occasion, has expressed his decided opinion that a separation of the administration of equity from that of the common law is wise and convenient. "All nations," says he, "have equity, but some have law and equity mixed in the same court, which is worse, and some have it distinguished in several courts, which is better;" and again, "In some states, that jurisdiction which decrees according to equity and moral right, and that which decrees according to strict right, is committed to the same court; in others, they are committed to different courts. We entirely opine for the separation of the courts; for the distinction of the cases will not long be attended to if the jurisdictions meet in the same person; and the will of the judges will then master the law."

Lord Hardwicke held the same opinion. Lord Mansfield, it is to be presumed, thought otherwise, for he endeavoured to introduce equitable doctrines into the courts of law. The old strictness has however been restored. His successor, Lord Kenyon, made use of these expressions: "If it had fallen to my lot to form a system of jurisprudence, whether or not I should have thought it advisable to establish different courts, with different jurisdictions, and governed by different rules, it is not necessary to say; but influenced as I am by certain prejudices that have become inveterate with those who comply with the systems they find established, I find that in these courts, proceeding by different rules, a certain combined system of jurisprudence has been framed most beneficial to the people of this country, and which I hope I may be indulged in supposing has never yet been equalled in any other country on earth. Our courts of law only consider legal rights; our courts of equity have other rules, by which they sometimes supersede strict legal rules, and in doing so they act most beneficially for the subject." In this country the principle of separating jurisdictions has been largely acted upon. We have our courts of equity and law; our bankrupt and insolvent courts, and courts of ecclesiastical and admiralty jurisdiction; indeed, until recent times, our several courts of law had, in principle, jurisdiction only over certain specified classes of suits. In countries governed by the civil law, the practice has in general been the other way. But whether the one opinion or the other be the more correct in theory, the system adopted by every nation has been mainly influenced by the peculiarities of its own institutions, habits, and circumstances, and the forms of its remedial justice. In all such cases the separation or union of the equitable and legal jurisdiction must be a mixed question of public policy and private convenience.

In some of the American States, the administration of law and equity is perfectly distinct; in others the administration of equity is only partially committed to distinct courts; in a third class the two jurisdictions are vested in one and the same tribunal; and in a fourth there are no courts exercising an equitable jurisdiction.

In most of our colonies the governor is invested with the jurisdiction of chancellor; but in some of the greatest importance where a judicial establishment of some magnitude is maintained, the chief or supreme court is invested with the chancery jurisdiction.

This attempt at the exposition of the general principles of what in this country is called equity seems to the writer of this article to be better suited to a work of this nature than a full description of the practice of, that is, the course of proceeding in, a suit in a court of equity. The practice or procedure of any court can hardly be made intelligible to any person but one who knows something of it by experience; and any technical description of it is useless unless it is minutely and circumstantially exact. It is desirable, however, that in addition to some knowledge of the subjects which belong to the jurisdiction of a court of equity, all persons should have some clear notion of the way in which the matters in dispute between parties to a suit in equity are brought before the court, and by what kind of proof or evidence they are established. It may also be useful that persons should have a general, and so far as it goes, a correct knowledge of the different modes in which such questions of fact are put in issue, and proved in our courts of law and equity. The following short outline of the course of proceeding in a suit of chancery, taken in connection with other articles in this work, such as CHANCELLOR, CHANCERY, DEPOSITION, and PLEADING, may probably, so far as it goes, give somewhat more information on the subject of equity jurisdiction than is found in books not strictly professional.

A suit in the courts of chancery is commenced by presenting a petition to the lord chancellor, containing a statement of the plaintiff's case, and praying for such relief as he may consider himself entitled to receive. This petition is technically called a Bill, and is in the nature of the declaration at common law [DECLARATION]; but if the suit is instituted on behalf of the crown, or a charity, or any of the objects under the peculiar protection of the crown, the petition is in the form of a narrative of the facts by the attorney-general, and is called an Information. There is also a petition termed an Information and Bill, which is where the attorney-general, at the relation (that is, the information) of a third person (thence called the relator) informs the court of the facts which he thinks are a fit subject of inquiry. The practice which governs all these proceedings is the same. It used to be the practice at the end of the statement in a bill to add what was called the interrogating part, consisting of the statements of the bill thrown into the form of distinct questions, and often expressed in terms of great length and particularity. But by a recent enactment, a bill no longer contains interrogations, which may, however, if thought requisite, be filed separately. The statements in the bill are not made upon oath; and further, in order to obtain a full and complete discovery from the defendant, both as regards the complaint and the supposed defence, various allegations are made in many cases from mere conjecture, and this practice, it has been considered after much laboured discussion, tends to the due administration of justice; for though doubtless many frivolous suits are instituted, yet, from the nature of cases of fraud and concealment, the plaintiff is often ignorant of the precise nature of the case, and frames his bill in various forms so as to elicit from the defendant a full discovery of the truth. Bills of this nature are called original bills, and either may be for discovery and relief, or for discovery merely.

When the bill is placed on the records of the court it is said to be *filed*, and the writ of subpœna issues commanding the defendant to appear and answer the allegations of the bill within a certain time

If, upon the face of the bill, it should appear that the plaintiff is not entitled to the relief prayed for as against the defendant, the defendant may demur,—that is, demand the judgment of the court upon the statement made by the plaintiff, whether the suit shall proceed [DEMURRER]; and if any cause, not apparent upon the bill, should exist why the suit should be either dismissed, delayed, or barred, the defendant may put in a plea, stating such matter, and demanding the judgment of the court, as in the case of a demurrer. But if neither of these modes of defence are applicable, and the defendant cannot disclaim [DISCLAIMER], he must answer upon oath the interrogatories in the bill according to the best of his *knowledge*, *remembrance*, *information*, and *belief*. This mode of defence is styled an Answer. All or any of these several modes of defence may be used together, if applied to separate and distinct parts of the case made by the plaintiff.

In the successive stages of a suit, references as to the pleadings, and as to facts, may be made to the judges in equity sitting at chambers, who conduct the routine part of the business through their chief clerks. These references were formerly made to the Masters of the court. If the defendant does not answer the bill with sufficient precision, the plaintiff may except to the answer for insufficiency. If the answer is decided to be insufficient, the defendant must answer further.

It frequently happens that, during the progress of the suit, from the discovery of new matter, the deaths and marriages of parties, and other causes, the pleadings become defective, and in these cases it is necessary to bring the new matter, or parties becoming interested, before the court. This is done by means of further statements, which are now introduced by way of amendments to the bill, or by obtaining leave of the court to revive a suit which has abated proceedings, which recent legislation has rendered very simple and rapid. Formerly the same thing was done by fresh bills, called supplemental bills, bills of revivor, or bills of revivor and supplement, according to the nature of the defect which they were intended to supply.

Pleas and demurrers are at once argued before the court: if allowed, the suit, or so much of it as is covered by the demurrer or plea, is at an end, though the court will generally permit the plaintiff to amend his bill where it is not apparent from his own statement that he cannot make any case against the defendant; otherwise the only object attained by the demurrer or plea would be to drive the plaintiff to file a new bill, omitting or amending the objectionable part. But if the demurrer or plea is overruled, the defendant is compelled to answer fully, just as if he had not demurred or pleaded. When the answer is filed, the plaintiff, if from the disclosures made he deems it advisable, may amend his bill; that is, erase such part of his statements as he no longer considers necessary, and insert other statements which may appear necessary to sustain his case; and the defendant must answer to this new matter.

In cases where the bill is for discovery only, and in some others, the answer puts an end to the suit; and when the object of the bill is to obtain an injunction, which is granted either upon affidavits before answer or in default of an answer, the suit is also ended, unless the defendant desires to dissolve the injunction. But where a decree is necessary, the case must come on to be heard either upon evidence taken before the examiners of the court or commissioners appointed for the purpose [DEPOSITION]; or where the plaintiff considers the disclosures in the answer sufficient, the cause is heard upon bill and answer alone, without further evidence, and this is at the plaintiff's discretion.

The cause is heard in its turn by the master of the rolls or the vice-chancellors, if instituted in the Court of Chancery; for the lord chancellor and lords justices rarely hear causes in the first instance. [CHANCERY.] If the nature of the suit admits, a final decree is made; or if any further inquiry be necessary, or any accounts are to be taken, references are made to the judge sitting at chambers for those purposes.

This is the form of the simplest suit in equity, and is sufficient to point out the successive steps necessary to be taken. Formerly suits were of a far more complicated character. Many special applications to the court might become necessary at various stages before the cause was ripe for hearing; and the references made to the Masters, their reports thereon, hearing on further directions, and fresh references, used frequently to consume much time. Under the present state of things, these matters are settled in a much more prompt way, and most successful efforts have been made to simplify and shorten procedure. The recent statute 15 & 16 Vict. c. 86, and some others, have so altered the practice that the old text-books have been nearly superseded. Those who wish for a more accurate knowledge of the proceedings in a suit in chancery may consult Daniell's 'Chancery Practice,' third edition.

The principal English treatises on equity are those of Mr. Maddock and Mr. Fonblanque: the former treats of his subject under heads devoted to the several subject matters cognisable in courts of equity; the latter considers it with reference to the jurisdiction exercised by courts of law, as concurrent, assistant, exclusive. The American treatise of Mr. Justice Story unites these two modes, and explains the subject in a masterly and scientific manner.

EQUU'LEUS PICTO'RIS (the Painter's Horse, or Easel), a constellation of Lacaille, situated close to the principal star of Argo. [CANOPUS.] Its principal star (α) is 583 of Lacaille, and 2260 in the Catalogue of the British Association.

ERA. [ÆRA.]

ERASTIANISM. [ERASTUS, in BIOG. DIV.]

ERATO. [MUSES.]

ERBIUM; (Er.) a metal discovered by Mosander associated with yttria. Its properties are but little known. Some of them are as follows:—Its oxide becomes of a dark orange colour when heated in contact with the air, which colour it loses with a little weight, when heated in hydrogen gas. It is to the presence of this oxide that yttria owes its yellow colour, when prepared as hitherto directed. The sulphate and nitrate of erbium are free from colour. It has not been reduced to the metallic state.

ERECHTHEIUM, a beautiful Ionic temple dedicated to Erechtheus, built near the western brow of the Acropolis at Athens, and at the time when Stuart visited the place forming part of the modern fortress of the Acropolis. Connected with this building, and placed on one side of it at the end of the cella, is a tetrastyle pseudo-dipteral Ionic portico, in the same style as the portico of the Erechtheium: and on the opposite side is a small roofed building supported by caryatides, placed on an elevated basement. [CARYATIDES.] The Erechtheium was thus, as Mr. Fergusson remarks, properly three temples grouped together, the whole presenting a singularly picturesque group of the most studied irregularity, though the separate features are as studiously symmetrical. The back wall of the cella of the Temple of Erechtheus is decorated with four semi-columns in antis engaged in the wall, and of the same order as the portico, which is hexastyle, and raised on three steps, forming a basement which runs round the entire building with its adjuncts. In Stuart's 'Athens,' the prothyrum is restored, and forms a closed chamber, for which there does not appear to be sufficient authority. It is more probable that the prothyrum was open, like some other Greek temples, because, as shown on Stuart's plan, the portico from its shallowness would be of little use as a covering, and would also produce little architectural effect. In the side portico, called Minerva Polias, which was most probably constructed after the Erechtheium, there was no opportunity of producing a depth of shadow by the deep recess of an open prothyrum, and the architect accordingly appears to have adopted the pseudo-dipteral portico to produce a somewhat similar effect, as well as to gain a covered space for those who officiated. It would appear from the regularity of the plan of the Temple of Erechtheus, that it was constructed before the other, and of that regular parallelopipedal figure most commonly employed in these buildings; and that at a later period the Pandrosium was constructed, with the portico on the opposite side forming the entrance or vestibule to the cella of the temple, which was formed from a part of the cella of the Temple of Erechtheus, cut off from the end of that cella, which was either at that time or previously lighted with windows.

The length of the Temple of Erechtheus is 73 feet 2 inches from the columns of the portico to those at the back of the cella; the width is 36 feet 6 inches. The depth of the portico of Minerva Polias is 21 feet 1 inch, and the width 33 feet 1 inch. The Pandrosium is 18 feet 4 inches wide, and 11 feet 9 inches deep. (Stuart's 'Antiquities of Athens,' edited by W. Kinnard, architect.) The columns of the Erechtheium are 2 feet 3·8 inches in diameter at the base, and 1 foot 11·2 inches at the upper diameter; and those of the Minerva Polias 2 feet 6·9 inches, and the upper 2 feet 3·5 inches: while the intercolumniations are respectively—Erechtheium 4 feet 7·95 inches, Minerva Polias 7 feet, 8·19 inches, although there is a slight variation in the intercolumns, which may be the effect of time and inaccuracy in setting them out originally. The columns of the Minerva Polias are on a much lower level than those of the Erechtheium. The capitals of the order of these two temples are very richly carved. The volutes are very graceful [COLUMN], and the spiral lines are elaborately arranged. The necking of the capital is enriched with leaves, as well as with an enriched ovolo and astragals, and the volutes are connected by an enriched twisted band or guilloche ornament. The shafts are fluted. But with regard to many peculiarities in the detail, we must refer to the plates in Stuart's 'Athens.' The entablatures have several of their members enriched, and are similar in design; the bases of the columns however vary. The height of the columns of the Erechtheium is 27 feet 7 inches, and of the Minerva Polias 25 feet. The pilaster of the Erechtheium is elegantly decorated, and the mouldings and decora-

tions are continued under the architraves. The height of the entablature of the Erechtheium is 4 feet 11 inches; and the height of the Minerva Polias is 5 feet 5 inches. The rise in the pediment of the portico of the latter is 3 feet 4 inches. The entablature of the Pandrosium is heavy; it is decorated with dentils, and also with pateræ on the upper face of the architrave. The windows and doors diminish at the top, and the friezes of the porticos appear to have been formerly decorated, if we may judge from the remains of cramps and cramp-holes on their faces. Some details respecting this building, not published in Stuart, are given in the 'Erechtheion,' a work on this edifice by H. W. Inwood, architect, who has imitated the Erechtheium and Pandrosium in the external design of part of St. Pancras Church, London. Stuart's 'Athens,' vol. ii., contains the plans, elevations, sections, and details of this building.

EREMACAUSIS. *Decay.* Eremacausis literally signifies slow burning; that is, gradual oxidation.

In popular language, the word decay is expressive of the constant retrogressive change of which matter is susceptible. The crumbling walls of an old ruin, the few hollow trunks in its vicinity, and the traces of life that once animated the scene, are familiar examples of a state of things that is somewhat loosely expressed by the term decay. A dead animal, under ordinary circumstances, soon commences to alter in colour, noxious odours are emitted from it, and an appeal is made to the eyes and nose of the observer sufficient to indicate that a considerable change from the normal condition of the animal is taking place. This change is generally denoted by the word decay, and consists in the gradual wasting or burning away of the animal by the *chemical* action of the oxygen of the air; by which all parts of it, except bones, are slowly and almost entirely resolved into gaseous compounds. Old walls crumble away, not by true decay, not by the chemical action of the oxygen of the air, but principally by the *mechanical* action of wind and rain.

In order therefore to avoid much ambiguity, it has long been the practice in scientific treatises, and is now becoming the general custom, to indicate decay proper by the term eremacausis. This term has also the advantage of perfectly describing what is known to take place.

Eremacausis, fermentation, and combustion, are phenomena that are frequently very intimately associated; but no difficulty will be found in assigning to each its proper limits, if it be remembered, first, that fermentation is simply a rearrangement of the constituents of a compound; second, that eremacausis is a slow oxidation of the compound at common temperatures; and third, that combustion is rapid oxidation of a compound at a temperature sufficiently high to produce light. [COMBUSTION; FERMENT.]

The natural processes of fermentation and eremacausis may be not inaptly compared with the artificial processes of dry distillation and combustion. In the manufacture of gas, for example, coal is heated in closed vessels (that is, it is submitted to dry distillation), when a rearrangement of the constituents of the coal takes place, and coal-gas, coal-tar, coke, &c., result. When, however, coal is burned in a common stove, then the same kind of change is produced as occurs in eremacausis, namely, a combination of the constituents of the coal with the oxygen of the air, but the process goes on at a sufficiently rapid rate and at a sufficiently high temperature to produce light, and is therefore denominated combustion.

Eremacausis is almost entirely confined to the animal and vegetable kingdoms. Few minerals are acted upon by the oxygen of the air, and even when this action does take place the change is never a retrogressive one. Iron pyrites, for example, a compound of sulphur and iron (FeS_2), undergoes slow oxidation on exposure to air, but the resulting compound, sulphate of iron (FeO,SO_3), is more complex than the pyrites.

Animals and vegetables grow or are built up by virtue of certain influences which are sometimes aggregated under the name *vital force;* and when these influences cease, not only does the progressive action terminate, but eremacausis commences, especially if air and moisture are present. Organised bodies are composed of matters called proximate principles. Such are, in vegetables, starch, cellulose, gluten, sugar, &c., while in animals some of these principles form fat, others blood, &c. These proximate principles are again composed of other substances, called ultimate principles or elements. The elements necessary to notice here, are carbon, oxygen, hydrogen, and nitrogen. Organised bodies get these elements from the inorganic world, that is, from the earth and atmosphere. Vegetables get carbon from carbonic acid (CO_2), a gas, composed of carbon and oxygen, and always present in the air; hydrogen and oxygen they chiefly obtain from water, and nitrogen from various sources, though the ultimate but indirect source is, no doubt, the atmosphere, of which four-fifths are nitrogen. In addition to these elements, vegetables contain bone-forming material (phosphate of lime, &c.), which they have obtained by their roots directly from the earth, and which material, after having performed its office of building up the animal skeleton, is again returned to the earth without going through re-composition, or decomposition. Some animals derive the elements enumerated, by feeding upon vegetables; whilst others derive these principles more directly by feeding upon animals. Thus are animal and vegetable organisms built up, but at every step the combination of forces above alluded to, is essential, and its action consists chiefly in the production of complex compounds from more simple ones; hence it might be expected that the elements composing these complex compounds having been, so to speak, drawn out of their first and most stable condition, should have a tendency to return to that state in which the forces that operated upon them are either removed or altered in direction. Such is indeed the case, and this retrogressive change, or eremacausis, soon commences after the cessation of life, and goes on at, according to circumstances, a slow or rapid rate. In illustration of eremacausis let us follow the element carbon through one or two of its circles of usefulness. Thrown into the atmosphere, from the combustion of coal or wood, under the form of carbonic, acid, it is absorbed and assimilated by plants, the oxygen of the carbonic acid being returned to the air. The leaves of the plant will probably die when winter comes, and then will either undergo thorough or partial eremacausis, the carbon being either slowly but completely burnt into carbonic acid and returned into the atmosphere, or partially oxidised and converted into humus, or vegetable mould.

Other parts of the plant are perhaps eaten by man or the lower animals, and their carbon thus becomes part of an animal body, there to do duty until chemical affinity, under the form of eremacausis, once more restores the carbon to the air as carbonic acid, only to pass again through the same cycle of changes.

The three remaining chief elements of organised bodies are also affected by eremacausis, the hydrogen being converted into water, and the nitrogen, either into nitric acid or ammonia, while the oxygen escapes either as water or carbonic acid.

Eremacausis appears essentially to precede and determine the processes of fermentation and putrefaction, and hence, if organic substances be rigidly excluded from contact with oxygen, they cannot be subject to either of these processes; since eremacausis can only occur in the presence of free oxygen. Advantage is taken of this fact to preserve meat and vegetables in all their original freshness, by enclosing them in air-tight canisters, from which atmospheric air has been carefully expelled. If the smallest trace of air be suffered to remain in the canisters or in the pores of the enclosed substances, eremacausis commences, and determines putrefaction, which latter process, once commenced, is scarcely retarded by exclusion of air, and thus it is that meats carelessly preserved are found, on opening the cases, to be utterly putrid. [FERMENT; PUTREFACTION.]

ERGOT, *Medical Uses of.* Ergot is a name bestowed upon a peculiar state of the seed of several cereal grains, but most frequently of the rye, which resembles a spur, or horn; hence, likewise, termed *Secale cornutum*, or *spurred* rye. Even the common rye-grass is liable to its attacks, and more rarely some cyperaceous plants. A partial list of these is given in the papers of Smith, Quekett, and Bauer, in 'Trans. of Linnæan Society,' vol. xviii. pp. 449–482, and a more complete one by Phoebus (Deutschl. Kryptogam. Giftegewächse. Berlin, 1838). Whether this state of the grain be merely an altered condition of the pistil, or the result of the puncture of insects, or of the development of a fungus, is doubtful; but the best authorities incline to the opinion that it is a fungus. (See Mr. Bauer's paper on the *Uredo fœtida* 'Supplement to the Penny Magazine,' March, 1833.) De Candolle considers the fungus to be the *Sclerotium clavus.* It is termed *Spermædia clavus* by Fries; *Sphacelia Segetum* by Lévillé; *Ergotætia abortifaciens* by Quekett; *Hymenula clavus* by Corda; and, lastly, *Oidium abortifaciens* (see Lindley, 'Medical and Œconomical Botany,' p. 14), by Berkeley, who considers it analogous to the parasitic fungus so destructive to the vines. The spur is of variable length, from a few lines to two inches, and is from two to four lines in thickness; when large, only a few grains in each ear are affected; when small, in general all of them are diseased. In colour the exterior or husk is of a bluish-black or violet hue, with two or three streaks of dotted gray; the interior is of a dull whitish or gray tint. It is specifically lighter than water, which affords a criterion for distinguishing sound from tainted grain. When fresh it is tough and flexible, but brittle and easily pulverised when dry. The powder is apt to attract moisture, which impairs its properties. Time also completely dissipates its peculiar qualities. A small *Acarus* attacks it. It is more potent in proportion to its freshness. "It has a disagreeable heavy smell (which being analogous to that of many fungi, strengthens the opinion that it belongs to that class of vegetable substances), a nauseous, slightly acrid taste, and imparts both its taste and smell to water and alcohol. Bread which contains it is defective in firmness, liable to become moist, and cracks and crumbles soon after being taken from the oven." [ERGOTIN.]

Bread prepared from grain which has a large admixture of the spur occasions very distressing and often fatal effects, which are shown more or less rapidly according to the quantity present in the food, and the circumstances in which those who use it are placed. These effects have been observed to be most serious in seasons of scarcity, when they produce dreadful disease—the *Raphanes* of Linnæus, Cullen, and other nosologists. The symptoms which result from spurred grain, when used for a considerable time, are of two distinct kinds, one of a nervous nature, characterised by violent spasmodic convulsions, the other a disordered state of the constitution, which terminates in the peculiar disease called Gangræna ustilaginea, or dry gangrene. A single dose of the spur, not diluted by admixture with sour flour, excites effects which vary according to the quantity taken and the state of the person, and are chiefly limited to the stomach and intestinal canal, if the dose be small; but if so much as two drachms be taken, it causes giddiness, headache, flushed face, pain and spasms in the stomach, nausea and vomiting, with colic, purging, and a sense of weariness and weight in the limbs. In the case of parturient females, when given at a certain stage of the labour, it is admitted by most practitioners and writers to produce specific effects, and to expedite the labour in a very marked manner. It is by some persons alleged to produce hurtful effects upon the child; but such consequences probably occur only when it has been used at an improper stage of the labour; or when it ought not to have been employed under any circumstances. The rules for its employment are given in works devoted to obstetrics, to which we refer. It has likewise been recommended in menorrhagia and in leucorrhœa, against the former of which it is most useful when dependent on debility.

The extraordinary effects of the ergot of rye have made it the subject of experiments in medicine. It has consequently become an article of commerce as a drug, and imported from the Continent. By an attentive observation of the circumstances which favour this disease in the rye, it might be profitable to cultivate the plant expressly for the ergot it produces. The seed which grows on the same ear with the ergot might be selected for seed, and a cold wet soil, with an ungenial aspect, might be chosen as most likely to perpetuate the disease, or steeping the most healthy seeds in water in which the sporidia of the *oidium abortifaciens* are contained, will, when planted, propagate the diseased form of the grain. The ergot is sold by druggists at from 10*s.* to 20*s.* per ounce, so that, if only a pound of ergot could be collected, it would be worth more than the produce in sound grain of an acre of the best land. At all events, it will well repay the trouble of picking out the ergot from the rye, where it is infected, and it is easily discovered, before reaping, from its prominence and black colour.

The nervous symptoms arising from the use of bread formed of spurred rye, may in general be cured by emetics, laxatives, and frequent small doses of opium, provided this treatment be adopted in reasonable time, and the unwholesome food completely withdrawn.

The tendency to dry gangrene is to be combatted by the use of cinchona and cordials, with local applications to the part threatened. The noxious food must be completely relinquished. (Christison 'On Poisons.')

This diseased condition of the seeds of certain grasses is also a matter of very great agricultural importance; its prevalence being the probable cause of much of the abortion of which dairy herds are sometimes the subject. A writer in the 'Agricultural Gazette' thus refers to the matter:—"In the western climate of this kingdom, the existence of this disease in the grasses of our pastures is by no means uncommon in the autumn of the year. An examination of the seed stems of our meadows will generally give evidence of the disease, but it is only when it is abundant that its influence is so manifest. Unfortunately much of the grass land in the moist climate of the west is too frequently the cause of trouble and loss by causing the abortion of the cows fed thereon. The disease is seldom found upon grass land which has been mown in the same season, and even when it is found its occurrence is so casual as to be of little importance. The land which has been grazed during the summer is that upon which the ergotised grass is found to exist most abundantly, because the stock having avoided the seed stems, these have been enabled to fulfil their special functions and produce seed which has subsequently become diseased. It is clear that if prevention is the object to be aimed at, this will be best attained by keeping breeding stock from land thus bearing a diseased produce. This may be accomplished on the majority of farms by removing the breeding cows and heifers from their summer pasturage, say in July, and keeping them afterwards upon land which had been mown that season. The removal of the stock should not be delayed until any case of abortion has positively occurred, because, that having once commenced it rapidly spreads through any herd, and often in opposition to every care. As soon as there is seed formed upon the seed-stems of the grass, the prudent breeder may take notice of danger, and his wisest policy will undoubtedly be to put his cows and heifers upon the after-grass. There are very many districts where the climate, from being dry, does not render this precaution necessary, but at the same time there are numerous tracts of land where the moisture of the climate acts upon the grass seeds, and favours the growth of ergotised grass, and such land is noted for the difficulty experienced in keeping the stock in proper breeding order. The age of the fœtus appears to be a matter of small importance, for it varies from two months upwards at the time when the abortion takes place. Some stock are much more sensitive to influences of this kind than others, and this is doubtless dependant upon their health and vigour; and thus stock which are well bred, *i.e.*, nearly related, are more liable to injury in this way than those which are inferior in this respect: for although by judicious breeding we improve the general character of an animal, yet at the same time this altered character is generally accompanied by diminished vigour.

"This explains how the best bred cows and heifers will often throw their calves, whilst some common stock about which the breeder is indifferent will frequently escape, although their treatment and food may be similar, and each may have partaken of this ergotised grass. Knowing as we do the action of this diseased form of grass seed, it becomes highly important that we should in this way avoid a cause so prolific of trouble and loss to many of our best breeders."

ERGOTIN is an active principle contained in ergot. [ERGOT, NAT. HIST. DIV.] It may be prepared by the following process, advantage being taken of its insolubility in water or ether and its solubility in alcohol. Powdered ergot is first thoroughly exhausted with ether by percolation, to get rid of fatty matter; it is then digested in boiling alcohol, filtered, the filtrate evaporated to the consistence of an extract, and the extract treated with water, which leaves the ergotin undissolved.

Ergotin has an acrid bitter taste, and, when warmed, a peculiar, unpleasant odour. It is soluble in caustic alkalies from which it is precipitated unchanged on addition of dilute acids. Strong sulphuric and acetic acids also dissolve it, dilution with water causing it to be again thrown down. It is infusible, and in contact with the air burns with a peculiar odour. Nitric acid decomposes ergotin.

Under the name of *Bonjean's Ergotin*, there occurs in pharmacy a preparation obtained by digesting the aqueous extract in alcohol and evaporating the solution to a proper consistence. As ergotin, properly so called, is in the pure state insoluble in water, it follows that Bonjean's preparation must owe its activity either to some other substance than ergotin, or that in the process for obtaining the aqueous extract, the ergotin is rendered soluble in water by the presence of other bodies in the ergot.

Ergotin is a poison, slow but deadly.

ERI'DANUS (the river Eridanus), a constellation first mentioned by Aratus, who calls it Eridanus. Hyginus states it to have been from the Nile, and assigns a reason [CANOPUS]; but the scholiast on Aratus states this to have been peculiar to the Egyptians. In the heavens it is a winding stream, not very well marked by stars, extending from a bright star (α) of the first magnitude, called Achernes, and situated near the southern part of Phœnix, past the feet of Cetus, and ending at the star Rigel in Orion. Its principal stars are as follows:—

ERIOMETER, an instrument invented by Dr. Thomas Young, for measuring the diameter of minute fibres, such as those of wool, whence the name (from ἔριον, wool, and μέτρον, a measure).

If we gently breathe upon a plate of glass, or scatter some very fine powder upon it, such as *Lycopodium* dust, and look through it at the sun or a candle, a number of rings of colour will be seen. There will be first round the luminous source a light area, terminating in a reddish dark margin; then a ring of bluish green, succeeded by a red ring, and these two last colours will be repeated several times if the particles are uniform in diameter. The effect is something like that produced by a halo round the sun or moon. As the diameter of the rings varies with the size of the particles, or fibres, it occurred to Dr. Young that the diameters of these minute bodies might be measured by determining the size of the rings produced by them. His eriometer consisted of a piece of card or a plate of brass with a hole about $\frac{1}{50}$th of an inch in diameter in the centre of a circle about half an inch in diameter, the circumference of which was perforated with eight or ten holes made as minute as possible. The fibres or particles to be measured are fixed in a slider, and the instrument being placed before a strong light, the observer, assisted by a lens behind the small hole, will see the rings. The slider must be drawn out until the limit of the first green ring and the red one coincides with the circle of perforations, and the index will then show on the scale the magnitude of the particles or fibres. The unit on this scale is that of the seed of the *Lycoperdon bovista*, which was ascertained by Dr. Wollaston to be

$\frac{1}{8500}$th of an inch in diameter, and as this substance gave rings which indicated $3\frac{1}{2}$ on the scale, it follows that 1 on the same scale is equal to the 29,750th of an inch, or in round numbers the 30,000th part. In order therefore to convert the following measurements, which are selected from Dr. Young's copious table, into parts of an English inch, we have only to multiply $\frac{1}{30000}$ by the number in the table which expresses the diameter. Thus blood, diluted with water and placed between two pieces of glass, exhibits the rings very finely; this gives the number 6 or 7; accordingly we have the diameter of its particles thus: $\frac{1}{30000} \times 7 = \frac{7}{30000}$ or $\frac{1}{4285}$th part of an inch.

Milk diluted (the rings indistinct)	3

By observing the fibres which compose the crystalline lenses of the eyes of fishes, Brewster was enabled to obtain some remarkable results as to their structure. They are noticed in his 'Treatise on Optics,' p. 114. [DIFFRACTION.]

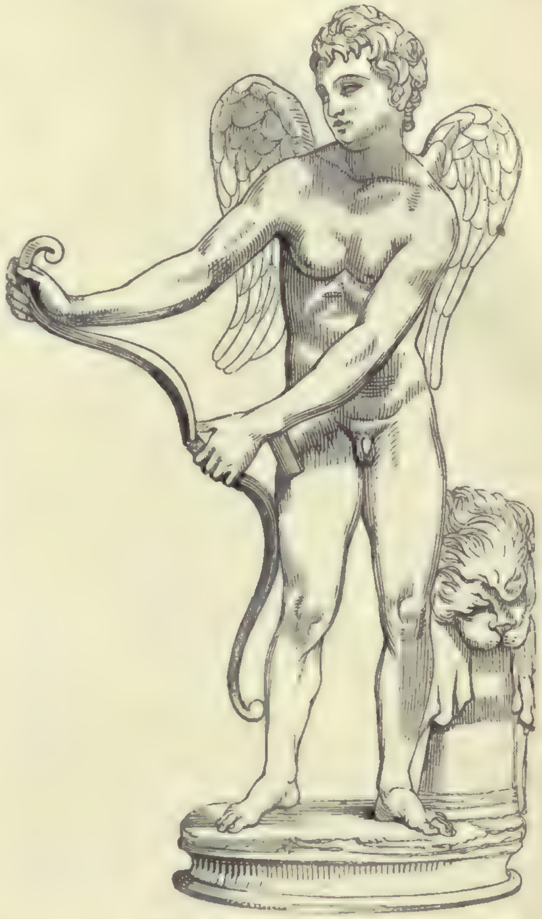
ERMINE, or ERMIN, one of the furs in heraldry, so called from the *Mustela erminea*, whose skin furnishes it. It is represented white, with black spots or tufts. The black spots in ermine are not of any determinate number, but are left to the discretion of the herald-painter.

EROS (Ἔρως), of the Greek mythology, Cupid or Amor of the Latin, was the god of love. The Eros of the early Greeks was a very different deity to the sportive god of the later mythology, or the Cupid of the Romans. The first mention of Eros occurs in the Theogony of Hesiod, where he is spoken of as one of the first among the gods in order of time, the ruler of the minds of gods and men. In the Symposium of Plato, in the Orphic Hymns, and elsewhere, he is also called the eldest of the gods; the idea in all being, that love the uniter was one of the primary causes of the existence of all living things.

Sometimes this Eros of the early cosmogony is spoken of as self-created or born without parentage. The later Eros is always regarded as the son of Aphrodite, but his father is variously said to be Hermes, Ares, or even Zeus. Hence there were enumerated both by Greek and Roman writers three deities, or rather three forms of the same deity, bearing the name of Eros or Cupid. The Eros of the amatory poets, the one usually meant when the name Eros or Cupid occurs without qualification, is the son of Hermes and Aphrodite (the Mercury and Venus of the Romans). The earlier Eros was represented as a young man of youthful mien; and even in later times the statues of the god in temples presented the appearance of a boy of graceful well developed form, and tender expression. The wanton and wilful child, delighting in cruel sport and wild mischief, belongs to a phase in art corresponding to that of the erotic poetry in literature.

The Eros of the later Greeks, and of the Romans, is still the god of love, but it is love in its merely sensuous form. Yet even when the original conception had become most degraded, something of the nobleness and purity of the old idea was preserved in the beautiful myth of Psyche [PSYCHE]; and in Anteros, the opposing dæmon, the avenger of neglected love, who is so frequently associated with Eros, there appears to be a reference to the old idea of the sanctity of love.

In extant works of art, Eros is frequently represented as a slender, winged youth bending his bow. This is the position in which he appeared in the famous bronze statue of Praxiteles described by Callistratus, and which was regarded as one of the great sculptor's finest works. There are two statues of this kind in the British Museum, and several in other collections, which are considered to be repetitions or imitations of the statue of Praxiteles. By later artists he was represented as a boy breaking the thunderbolts of Zeus, or the insignia of the other gods; riding on a lion, or playing with and subduing other wild animals, typifying in all the resistless power of love. Sometimes he appears with Psyche as a beautiful girl; sometimes with her as a butterfly. Sometimes he accompanies Aphrodite; at others he appears attended by Anteros. The later sculptors and vase painters, and generally the artists of the Roman period, represented him in accordance with the descriptions of the amatory poets, as a winged child armed with bow and arrows, as an emblem of the inspiration of love, through the eye, from a distant object. Eventually they figured an unlimited number of Erotes,—always children and almost always winged—playing about in every variety of attitude, in the air and on the water, as well as on land; attending Aphrodite; sporting with dolphins; binding lions; sporting with tame, or driving wild, animals; gathering fruit; disguised as torch-bearers at weddings; as captives, encaged, or hiding in nests—and, in short, in every way which an unrestrained fancy could invent, when the religious idea had become entirely dissociated from the deity. Athenæus (xiii. 2) quotes a beautiful passage from the Phædrus of Alexis, to show the impossibility of representing Eros to the senses.



Eros. From British Museum.

Thespiæ, on the eastern slope of Mount Helicon, was the chief seat of the worship of Eros. The ancient symbol of the god was a rude stone; but afterwards Praxiteles' famous statue of Eros was placed here, and attracted to Thespiæ nearly as many strangers as his statue of Aphrodite attracted to Cnidus. A broken stone inscribed with the name of Praxiteles is said to be still remaining among the ruins at Thespiæ. It was at Thespiæ that the Erotidia, or games in honour of Eros, were celebrated every fifth year. Nothing is known of the Erotidia except that they were celebrated with great solemnity; that music and various athletic games were performed; and that large numbers of strangers flocked to Thespiæ in order to be present at them. At Athens the altar of Eros stood at the entrance to the Academy.

ERRHINES (from *en* (ἐν), and *rhin* (ῥιν), 'the nose'), medicines which are applied to the nostrils, and which cause an increased flow of the secretion of the membrane which lines them, and often of the contiguous cavities and sinuses; frequently also occasioning sneezing, and an unusual secretion of tears. Snuffs of different kinds are familiar examples of this class of substances, and these generally cause sneezing, at least when first employed; but others, such as the turpeth mineral, merely produce increased secretion of the membrane. Where sneezing ensues, a considerable shock is felt over the whole frame, and of this effect advantage is sometimes taken to change the action of the system, or to remove morbid impressions, as when certain fits are impending, or for more limited purposes, such as dislodging any foreign body from the nose. The secondary effect of errhines is more frequently desired to give relief to the loaded vessels, by exciting them to increased secretion. Hence they are used in various diseased conditions of the organ of smell, and even of the neighbouring organs, being supposed to influence the vessels of the eye, and even of the brain. Some affections of the eye, and also of the head, are certainly relieved by such means, and their occasional use may be permitted; but the habitual use of errhines is in most cases objectionable, and followed by hurtful consequences. The membrane of the nose becomes thickened, its sensibility impaired, and the power of discriminating odours greatly lessened; while, if the substance be possessed at the same time of narcotic qualities, such as snuff procured from tobacco, the palate, the stomach, and other organs concerned in digestion likewise suffer, and loss of appetite with other symptoms of indigestion result. [STERNUTORIES.]

ERROR (in Law), a fault in the pleadings or in the process, or in the judgment, upon which a writ, called a Writ of Error (breve de errore corrigendo), might, and in some cases may, still be brought to reverse the judgment. The proceeding of bringing error, which now in ordinary cases consists of simply suggesting that "there is error in the record and proceedings," is the ordinary mode of appeal from a court of record, and is in theory a commission from the crown to the judges of a court superior to that in which the judgment was given, by which they are authorised to examine the record, and on such examination to affirm or reverse the judgment according to law.

ERUCIC ACID ($C_{44}H_{72}O_4$), a colourless crystalline acid contained in the expressed oil of mustard (*Sinapis alba*). It fuses at 93° Fahr., is insoluble in water, but soluble in alcohol and ether.

ERYSI'PELAS (*Ignis Sacer, the Rose, St. Anthony's Fire*), an inflammation of the skin, occasioning a spreading redness, which occupies a broad surface, on which are formed vesicles or blisters, preceded by and accompanied with fever. The whole of the inflamed surface is painful; but the pain is not acute, it is rather a sensation of burning or stinging than of severe pain. The redness is not intense like that produced by phlegmon or boil, but is of a pale rose colour. There is always considerable tumefaction; the tumour is not surrounded by a definite boundary, but is diffuse, irregularly circumscribed, and unattended with a sensation of throbbing. The tumour is often soft and boggy. It is characterised by the vesications which form upon it.

The proper seat of erysipelas is the skin, but the appearance of the disease is somewhat modified according to the part of the skin which is more especially inflamed. If the rete mucosum, or the part of the skin which is placed immediately beneath the cuticle [SKIN], be the principal seat of the inflammation, the vesication is remarkable; there is commonly a considerable discharge from the vesicles, and a free exfoliation of the cuticle. If, on the contrary, the inflammation be chiefly seated in the cutis vera, or the true skin,—namely, that portion of the skin which lies immediately beneath the rete mucosum,—the cellular tissue beneath the skin is always more or less involved in the inflammation, and then the tumefaction is considerable on account of the infiltration of the cellular tissue with serum poured out from the blood by the inflamed cuticle.

Erysipelatous inflammation is characterised by its tendency to spread, and thereby to cover a considerable portion of the external surface of the body. It creeps on in succession from one part of the skin to another until it extends to a great distance from the part originally attacked, the inflammation often disappearing from the former as it becomes established in the latter. Sometimes the inflammation appears to pass from the external surface to the internal organs; and occasionally the disease quits the surface as it attacks the internal organs, although more commonly the external and internal inflammation go on simultaneously, greatly increasing the severity and danger of the attack.

Erysipelas most commonly attacks the face, but it sometimes seizes on one of the extremities. The disease is always more severe when it attacks the head than when it is seated in any other part of the body.

The inflammation which appears on the external surface of the body in erysipelas is not the primary and essential part of the disease, but a remote event depending on a preceding state of disease affecting the whole system. This is proved by the fact that constitutional disturbance always precedes, commonly for the space of two or three days, the appearance of the local affection.

An attack of erysipelas comes on either with chills or a distinct cold shivering, attended with a sense of lassitude, aching in the limbs, restlessness, and that disordered state of the skin which has been expressively termed febrile uneasiness. There is from the beginning uneasiness or confusion in the head, which soon amounts to decided pain. This is accompanied with such a degree of drowsiness that the attack may sometimes be predicted long before there is any appearance of redness or swelling in the face, from the inability of the patient to keep himself awake. The chilliness is soon succeeded by heat of skin; the appetite fails; the bowels are constipated; the tongue is dry and parched; there is sometimes nausea and vomiting; the pulse is always frequent, sometimes full, soft, and compressible, but occasionally hard and tense.

After these symptoms have continued some time, always one, generally two, and sometimes three days, there appears on some part of the face a redness, attended with burning heat and tingling. Commonly a red spot appears on one cheek; after a short time a similar spot appears on the other cheek; often the redness spreads successively from one cheek to the other across the nose, which is completely involved in the affection. From the nose it extends to the forehead, and thence over the whole scalp. Soon after the redness appears the face begins to swell; and by the second night or the morning of the third day from the commencement of the fever, the eyes are completely closed, the eyelids exceedingly prominent, the nose distended, and the ears tumid, red, shining, and burning. On the fourth or fifth day the vesications appear on the inflamed surface, which break on the fifth or sixth, when the redness changes to a yellowish hue. The whole face is now so turgid that the form and expression of the features are completely lost, and the patient could not possibly be recognised by his most intimate friends.

The surface of the skin in the blistered places becomes covered with a brownish or dark-coloured scab, which often gives a livid or blackish appearance to the part; but this livid colour seldom goes deeper than the surface, and does not proceed from any degree of gangrene affecting the skin. On the parts of the face not affected with blisters the cuticle is destroyed, and desquamates, a new cuticle being formed beneath it. Though the face, in general, however intensely inflamed, seldom goes into suppuration, yet it is by no means uncommon for matter to form in the tumid eyelids.

Occasionally, though not often, when erysipelas attacks the face, it extends to the mouth and fauces, and even to the pharynx and larynx, at the same time that it covers the neck and chest externally. Dr. Copland mentions a case in which the enormous tumefaction of the neck and throat with the affection of the larynx and trachea, increased by the constriction produced by the integuments surrounding the neck and throat, caused suffocation in a few hours. When the inflammation extends to the fauces, throat, and larynx, it sometimes produces a species of croup.

On whatever part of the body the inflammation appears in erysipelas, even when it is strictly confined to the skin, its appearance is not attended with any remission of the fever which preceded it: on the contrary, the fever generally increases with the augmentation and extension of the inflammation.

The progress of the disease is more or less rapid, and its duration longer or shorter, according to the age, the temperament, and the vigour of the individual. In the young, the sanguine, and the robust, the tumefaction is sometimes fully formed on the second day, and the whole terminates on the sixth or seventh, while in the aged and the less vigorous it may be protracted to the tenth or twelfth, and the desquamation may not be completed before the fourteenth day. The average duration of the disease may be stated to be from eight to ten days.

When the fever and inflammation are intense, delirium comes on, which sometimes rapidly passes into coma. These are most alarming symptoms, indicating a severe and too often a mortal inflammation of the brain. In such cases death frequently takes place, with many of the symptoms of apoplexy, on the seventh, ninth, or eleventh day of the disease. "In such cases," says Dr. Cullen, "it has been commonly supposed that the disease is translated from the external to the internal parts. But I have not seen any instance in which it did not appear to me that the affection of the brain was merely a communication of the external affection, as this continued increasing at the same time with the internal. When the fatal event does not take place, the inflammation, after having affected a part, commonly the whole of the face, and perhaps the other external parts of the head, ceases. With the inflammation the fever also ceases; and, without any evident crisis, the patient returns to his ordinary state of health."

In the cases which prove fatal, on the examination of the body after death, the inflamed skin is found infiltrated with serum, which is sometimes mixed with pus, and occasionally portions of the skin are found disorganised, and in a state of gangrene. It is remarkable that the blood in the large vessels and in the cavities of the heart is semifluid, and that the veins which proceed from the inflamed parts are in a state of inflammation, and contain pus, more especially when the inflammation has extended from the skin to the cellular tissue and has passed into suppuration. In the cases attended with delirium and coma the membranes of the brain, and especially the arachnoid, are thickened and opaque with the effusion of serum between the membranes and into the ventricles. If the disease has been complicated with inflammation of the fauces, pharynx, œsophagus, trachea, and bronchi, these organs present the ordinary signs of inflammation; and the same is true with regard to the mucous membrane of the stomach and intestines; but in all these cases the signs of inflammation are much more closely allied to those which occur in fever than to those which are proper to pure inflammation.

There is a peculiar condition of the skin which seems to predispose to erysipelas connected with the irritable or bilious temperament, and a plethoric habit of the body. The occurrence of the disease once renders the skin peculiarly susceptible to its recurrence. Unwholesome and indigestible food, the excessive use of spirituous liquors, the suppression of the excretions, and more especially the suppression of the perspiration, of the bile, and of the catamenial discharge, predispose to erysipelas.

The exciting causes are exposure to cold and moist air after the body has been previously heated; exposure to sudden and great alternations of temperature: exposure to great heat however produced, whether by the direct rays of the sun or by a fire; intemperance;

unwholesome articles of diet, as shell-fish, or stale and rancid fish; rich, oily, fat, or smoked meats; impure states of the atmosphere; an impure state of the body, arising from a morbid condition of the blood, in consequence of the suppression of its depurating processes, whence the frequent occurrence of the disease in the advanced stages of fever, greatly complicating the state of fever and exhausting the little remaining strength of the patient. Violent emotion of mind has also been observed to be an exciting cause of erysipelas in those powerfully predisposed to the disease; in whom also local irritants often induce it, as wounds or punctures in the skin, the bites of leeches, the stings of insects, inoculation with variolous or vaccine matter. Instances are on record in which both variolous and vaccine matter have produced in children of irritable habits, two or three days after inoculation, an erysipelatous inflammation which has proved fatal.

Erysipelas is a disease capable of being propagated by contagion. Dr. Bateman has noticed that in several hospitals it has prevailed in certain wards, among patients admitted with different complaints. Dr. Wells has collected several examples of the communication of erysipelas by contagion, which occurred in private families. Such cases are rare, and perhaps never happen in well ventilated and cleanly houses. From the Royal Infirmary, at Edinburgh, this disease, like the puerperal fever, has been banished by ventilation, white-washing, and other means of purification.

The danger of erysipelas is in proportion to the intensity of the inflammation, and the severity of the affection of the brain. The danger is also imminent when there is great tumefaction of the throat, or when the inflammation spreads to the respiratory passages and the respiratory organs. As long as the inflammation is confined to the external surface, and the fever remains moderate, the brain not much affected, and the heart's action not inordinate, a favourable termination of the malady may be expected. The different varieties or species of the disease are also attended with very different degrees of danger. Authors usually describe four species, namely, the phlegmonous, the œdematous, the gangrenous, and the erratic. The phlegmonous is that form of the disease in which the inflammatory state of the system is the most distinctly marked. In the œdematous the fever and inflammation are less intense; but the tumefaction is so great that the appearance of the face resembles that of a bladder distended with water. This form of the malady most commonly affects persons of debilitated constitutions, who have been previously attacked or are simultaneously affected with dropsy, or some other chronic disease, incident to a cachectic state of the system, and induced commonly by habitual intemperance. It is always attended with considerable danger, for the disorder of some internal function increases with the advancement of the external disease. Very frequently delirium and coma come on at the height of the disease, and terminate fatally on the seventh or eighth day; or, in other cases, the symptoms continue undiminished, and death occurs at a later period. When this form of the disease attacks one of the extremities, it is attended with but little danger.

In the gangrenous form of the disease the colour of the affected part is of a dark red, and scattered vesicles with a livid base appear upon the surface, which frequently terminate in gangrenous ulcerations. Suppuration and gangrene of the muscles, tendons, and cellular tissue often take place, producing little caverns and sinuses, which contain an ill-conditioned pus, together with sloughs of the mortified parts, which are ultimately evacuated from the ulcers. It is accompanied with symptoms of low fever, in the progress of which delirium comes on, soon followed by coma. It is always a tedious and precarious and often a fatal form of the disease.

In the erratic species the inflamed patches appear one after another in different parts of the body, thus travelling in succession from the face to the neck and trunk, and from the trunk to the extremities. It often happens that each accession of the complaint is less and less severe as it recedes to a greater distance from the part first affected, and this form of the disease commonly terminates favourably in a week or ten days.

In the phlegmonous species, characterised by the presence of inflammatory fever, the method of treatment must be widely different from that proper to the œdematous and gangrenous, in which there is the very opposite state of the system. In the young, the plethoric, the sanguine, and the robust, at the commencement of the attack, when there is much pain in the head, when the heat of the skin is intense, and the pulse is full and strong, the remedies proper in any other case of inflammatory fever are required. In such cases there is sometimes danger that the disease will terminate in fatal inflammation of the brain, unless there be a free abstraction of blood. But it must be borne in mind that erysipelas does not ordinarily occur in the youthful and vigorous constitution; that it is not often accompanied with the signs of acute inflammation; that blood-letting is required only when acute inflammation is present, and that the extent of the bleeding must be strictly regulated by the degree of the inflammatory action. In an ordinary attack of phlegmonoid erysipelas, general bleeding is not necessary, at least in the constitutions commonly found in a crowded city. Moderate purging, diaphoretic and saline medicines strict confinement to bed in a cool apartment, with the diet appropriate to febrile diseases, are all the remedies required. If local bleeding and blistering appear to be indicated, care must be taken not to apply the leeches or the blister near the inflamed surface. Various applications to the inflamed surface have been recommended, the most common of which is flour, or some other absorbent powder, to imbibe the fluid which oozes from the vesications. The utility of such applications is doubtful. "The application of powdery substances," says Dr. Bateman, "has commonly, according to my own observation, augmented the heat and irritation in the commencement; and afterwards, when the fluid of the vesications oozes out, such substances produce additional irritation, by forming, with the concreting fluid, hard crusts upon the tender surface. In order to allay the irritation produced by the acrid discharge from the broken vesications, Dr. Willan recommends us to foment or wash the parts affected from time to time with milk, bran and water, thin gruel, or a decoction of elder-flowers and poppy-heads. In the early state of the inflammation, when the local heat and redness are great, moderate tepid washing, or the application of a cool but slightly stimulant lotion, such as the diluted liquor ammoniæ acetatis, has appeared to me to afford considerable relief." The local application of nitrate of silver is in some cases very beneficial.

In the œdematous species, when it occurs in broken-down constitutions, the result of habitual intemperance, even purgatives must be very cautiously administered; the strength must be sustained by mild nutritive diet and tonics, as cinchona or quinine, and even stimulants, as camphor, wine, or the beverage to which the patient has been habituated, are required. The aperients employed should be mild alterative mercurials, with equal parts of castor-oil and the spirit of turpentine administered perhaps every alternate morning.

In the gangrenous species, quinine in considerable doses through the whole course of the disease, opium, camphor, the mineral acids, wine, brandy, and the general regimen adapted to gangrenous affections occurring under other circumstances, must be freely employed. The remedies indispensable in the phlegmonoid species would be fatal in this form of the disease, while the remedies which afford the only chance of saving life in the latter would produce fatal inflammation of the brain if administered in the former.

ERYTHEMA, a superficial redness of some portion of the skin, varying in extent and form, attended with disorder of the constitution, without vesications, and uninfectious. It is distinguished from erysipelas by the slight degree of constitutional disorder, by the slight degree of local pain, by the more uniformly favourable termination of the disease, and by the absence of tumefaction and vesication.

Authors describe several species of this affection, namely:—

1. The fugacious (*Erythema fugax*), consisting of red patches of an irregular form, resembling the redness produced by pressure. These patches appear successively on the arms, neck, breast, and face. This affection is generally indicative of and produced by some disorder of the digestive organs.

2. The shining (*Erythema læve*), exhibits a uniformly smooth shining surface, and chiefly appears on the lower extremities in confluent patches. It is sometimes symptomatic of disorder of the digestive organs; occasionally attends the catamenia in delicate and irritable females, but most commonly accompanies anasarca or œdematous swellings. Under whatever circumstances anasarca occurs, so as greatly to stretch the skin, this Erythema is liable to be produced, and is often chequered with patches and streaks of dark red and purple hue. It commonly terminates in extensive desquamation of the skin, and may be considered as merely a modification of œdematous erysipelas.

3. Marginated (*Erythema marginatum*), occurs in patches which are bounded on one side by a hard elevated tortuous red border, in some places obscurely papulated; but the redness has no regular boundary on the open side. The patches appear on the extremities and loins in old people, and remain for an uncertain time, without producing any irritation in the skin. They are connected with some internal disorder, and may be considered as indicative of serious and dangerous diseases.

4. Papulated (*Erythema papulatum*), appears chiefly on the arms, neck, and breast, in irregular extensive patches, and most frequently in females and young persons. The patches are of a bright red hue, often slightly elevated; and for a day or two before the colour becomes vivid they are rough or imperfectly papulated. The redness afterwards continues for several days; and, as it declines, assumes, in the central parts, a bluish or pale purple tinge. This variety is generally attended by a tingling sensation, passing to soreness as the colour changes; and sometimes with much constitutional disturbance,—with a frequent small pulse, loss of appetite, depression of strength and spirits, watchfulness, and pains or tenderness of the limbs, but the general disorder is trifling.

5. Tuberculated (*Erythema tuberculatum*), is merely a slight modification of the advanced stage of the papulated.

6. Nodose (*Erythema nodosum*), consists of large oval patches on the fore part of the legs; the long diameter of the patch is parallel with the tibia; these patches slowly rise into hard and painful protuberances, and as regularly soften and subside in the course of nine or ten days. The red colour turns bluish on the eighth or ninth day, as if the leg had been bruised. It chiefly affects children, and particularly females, and is very seldom observed in boys. It is preceded by slight febrile symptoms for a week or more, which generally abate when the erythema appears. It is sometimes connected with the approach of the

catamenia, and its premature disappearance is not unfrequently succeeded by dangerous internal disease, as inflammation of the lungs.

The primary causes of erythema are the friction of contiguous parts, especially in fat persons; the accumulation of morbid secretions and excretions on the skin, as the matter of the perspiration, of the leucorrhœal discharge, of the catamenia, and of the alvine and urinary evacuations, in the adult in the course of other diseases; and in the infant in consequence of a want of proper ablution. It is also constantly produced by irritating articles of food and drink, and is the sign and the result of a disordered state of the digestive organs.

In most cases the affection disappears soon after the removal of the cause which produces it—by free ablution where it is the result of irritating matters on the skin; its disappearance is assisted sometimes by the application of an absorbent powder to the inflamed surface, and at other times by the use of a gentle stimulating lotion, as the spirit wash. When the disease is dependent on a disorder of the digestive organs, it can be removed only by the remedies proper for the removal of the stomachic, the hepatic, or the intestinal derangement. For the restoration of these organs to their sound condition, the most appropriate remedies are light diet, diaphoretics, the mercurial alteratives in combination with gentle aperients, and the mineral acids as tonics. (Bateman's 'Practical Synopsis of Cutaneous Diseases;' Copland's 'Dictionary of Practical Medicine.')

ERYTHRELLIC ACID. [ERYTHRIC ACID.]

ERYTHRIC ACID ($C_{32}H_{16}O_{16}$?). *Erythrin.* This acid was first discovered by Heeren in the *Roccella tinctoria*, a lichen from which is prepared a colour used in dyeing. It has since been found in other lichens used for the same purpose, and has been particularly examined by Stenhouse and Schunk. From erythric acid are derived *Erythrellic acid*, *Picroerythrin*, and *Erythro-mannite*. *Orcin* is also a derivative, but as it likewise exists ready formed in several of the lichens, and is moreover of considerable importance, it will be treated of in a separate article. [LICHENS, COLOURING MATTERS OF.]

Erythric acid may be readily obtained from the *Roccella* in which it exists to the extent of ten or twelve per cent., by digesting that lichen in water for a few hours, and then adding slaked lime. The acid unites with the lime, forming a salt that dissolves in the water. To the strained liquor hydrochloric acid is added, which precipitates the erythric acid in a gelatinous state. Collected on a filter, washed with a little cold water, the water removed by pressure, and the cake dissolved in warm alcohol, the acid is obtained on cooling in stellate groups of acicular crystals. The acid must not be boiled with alcohol, or a compound ether is formed.

Erythyric acid is colourless, tasteless, and odourless; it is soluble in 140 parts of boiling water, almost insoluble in cold water, and tolerably soluble in warm alcohol or ether. By beat it is decomposed, orcin at the same time being produced as a sublimate. Long boiling with water converts erythric acid into *picroerythrin*, with evolution of carbonic acid,

$$\underbrace{C_{32}H_{16}O_{16}}_{\text{Erythric acid.}} + 4HO = 2CO_2 + \underbrace{C_{30}H_{20}O_{16}}_{\text{Picroerythrin.}}$$

Erythric acid is precipitated by subacetate of lead; the compound formed contains 59·12 per cent. of oxide of lead.

Erythric acid dissolves in ammonia, yielding on exposure to air a deep purplish-red solution. It also dissolves in the fixed alkalies and their carbonates, from which solutions stronger acids reprecipitate it unchanged. Continued ebullition with baryta or lime coverts it into orcin, with production of a carbonate of the base:—

$$\underbrace{C_{32}H_{16}O_{16}}_{\text{Erythric acid.}} + 4BaO = 4(BaO, CO_2) + \underbrace{2(C_{14}H_8O_4)}_{\text{Orcin.}}$$

Erythrellic acid is produced to a greater or less extent during the process just mentioned. It crystallises in small thin plates, and is very similar, if not identical, with orcellic acid.

Picroerythrin ($C_{30}H_{20}O_{16}$?) is, as before indicated, a product of the action of boiling water on erythric acid. On concentrating the solution it is deposited in yellowish crystals, which may be obtained colourless by re-solution in boiling water and treating with animal charcoal.

Picroerythrin is very soluble in hot water, sparingly so in cold. It has a very bitter taste, is not altered by prolonged boiling with water, does not etherify alcohol, readily dissolves in the fixed alkalis, and by heat gives a sublimate of orcin. Its solution in ammonia rapidly becomes red on exposure to the air. Boiled with baryta, or lime-water, picroerythrin is converted into orcin, *erythro-mannite*, a carbonate of the base, being at the same time formed.

$$\underbrace{C_{34}H_{20}O_{16}}_{\text{Picroerythrin.}} + 4HO + 2BaO = 2(BaO, CO_2) + \underbrace{C_{14}H_8O_4}_{\text{Orcin.}} + \underbrace{C_{14}H_{16}O_{12}}_{\text{Erythro-mannite.}}$$

Erythro-mannite ($C_{14}H_{16}O_{12}$ + Aq.?), (*pseudo-orcin*, *erythro-glucin*,) may be obtained directly from the *Roccella* by boiling for several hours in lime-water, filtering, removing the lime by a current of carbonic acid, and concentrating the liquid to a syrupy consistence. From the cold gummy mass orcin is extracted by alcohol or ether, and the erythro-mannite obtained pure by re-crystallisation from boiling alcohol.

Erythro-mannite is very soluble in water, the solution yielding on evaporation very fine pyramidal crystals. It has a sweet taste, but is not fermentable. It is neutral to test-paper.

The name erythro-mannite was given to this compound by Stenhouse on account of its properties being very analogous to those possessed by mannite. [MANNITE.] Its homology with mannite is further confirmed by its yielding under similar circumstances a body very like nitro-mannite.

Nitro-erythro-mannite ($C_{14}H_{10}(NO_4)_6O_{12}$?) is obtained by dissolving erythro-mannite in fuming nitric acid, kept perfectly cold. On adding rather more than an equal bulk of strong sulphuric acid, and setting aside the mixture for a short time, a large quantity of minute crystals are formed; these may be separated from the mother liquor by draining in a funnel plugged with asbestos, and washing with water. From solution in alcohol the compound is obtained in beautiful crystals resembling benzoic acid.

Nitro-erythro-mannite fuses at 142° Fahr.; at a higher temperature it burns with slight deflagration. Mixed with a little sand, and placed on an anvil, it detonates violently on being struck with a hammer. Its solution is quite neutral to test-paper.

ERYTHRIN. [ERYTHRIC ACID.]

ERYTHRO-GLUCIN. [ERYTHRIC ACID.]

ERYTHROLEIC ACID (?), an acid of uncertain composition, said to be contained in *Roccella tinctoria*.

ERYTHROLEIN. [LICHENS, COLOURING MATTERS OF.]

ERYTHROLITMIN. [LICHENS, COLOURING MATTERS OF.]

ERYTHRO-MANNITE. [ERYTHRIC ACID.]

ERYTHROPHYLLE, the substance to which the autumnal red tint of some leaves is due. It is soluble in water and alcohol. Alkalies colour it brown, whilst salts of lead precipitate it of a beautiful green colour.

ERYTHROPROTIDE, a red extractive matter of uncertain composition, obtained from albuminous substances.

ERYTHROZYME. [MADDER, COLOURING MATTERS OF.]

ERYTRARSIN ($C_8H_{12}As_6O_6$), a red amorphous substance formed when cacodyl is burnt with a supply of air insufficient for its perfect combustion.

ESCAPEMENT. [HOROLOGY.]

ESCARP, or **SCARP**, in fortification, is that side of the ditch surrounding or in front of a work, and forming the exterior of the rampart. In field-works the escarp is usually formed by cutting the earth at such an inclination as will permit it to support itself, which may be at 45 degrees with the horizon, or more, according to the tenacity of the soil; and, to impede the enemy in attempting an assault, fraises or inclined palisades are frequently planted on the slope. In large fortresses the escarp is the exterior surface of the revetment wall which supports the rampart, and it is frequently formed at such an inclination that the base of the slope is to its height as 1 to 6; that is, it has a slope of ⅙. But engineers at present recommend that the exterior surfaces of both the escarp and counterscarp revetments be made vertical, in order to lessen the action of the weather upon the brick-work, and to prevent the formation of vegetation on the disintegrated brick-work and the accumulated dirt in the joints. [REVETMENT.]

ESCARPMENT, a precipitous side of any hill or rock. In military operations ground is frequently scarped, as it is called, or cut away nearly vertically about a position, in order to present an obstacle to an enemy. Part of the rock of Gibraltar has been rendered inaccessible in this manner; and in the execution of the entrenchments about Lisbon, in 1810, the British troops formed an escarpment from 15 to 20 feet high, and about two miles long, on the brow of a ridge of heights extending from Alhandra to the valley of Calandrix, in order to secure the line against an attack at that part. A similar work was executed along a ridge of hills between Mafra and the mouth of the S. Lorenzo.

ESCHAROTICS (ἐσχαρωτικά, from ἐσχαρόω, to form a crust, or scab) are agents applied to the surface of the body, which destroy the vitality of the part which they touch, and produce an eschar. This effect they occasion either by combining chemically with the animal matter, or by destroying the old affinities, and causing the elements of the part to enter into new combinations. Their action is more energetic in proportion to the degree of vitality of the part to which they are applied. They are classed under two heads, the *potential* cauterants, and the *actual* cautery: the former are chiefly chemical agents, and form new compounds with the elements of the part with which they come in contact; but some merely cause irritation and augmented absorption, and are distinguished as *erodents*. The actual cauterants are substances of an elevated temperature, which decompose the part which they touch, and completely destroy its organisation.

The chief potential cauterants are strong mineral acids, such as the sulphuric or nitric, pure alkalies, and some metallic salts, especially nitrate of silver, or lunar caustic. These are used either to produce counter-irritation, or to remove fungus or morbid growths. Lunar caustic seems to possess peculiar properties, and is unquestionably the most powerful *direct* antiphlogistic agent known. If applied in the solid state to many inflamed parts it speedily checks the morbid action, and is decidedly the best application to chilblains, and in leucorrhœa. The actual cauterants are used either for their primary action, viz., the immediate destruction of the part, or for their secondary effects. The former object is rarely attempted, except to prevent the absorption of any poisonous or contagious matter, such as the venom of a snake, or bite of a mad dog. The secondary effects are more important, and more varied according to the degree of heat of the substance applied. The first effect is pain more or less severe, a flow of blood towards the part, and more rapid performance of the process of interstitial deposition and absorption, terminating in inflammation, extending to a greater or less depth, according to the intensity of the heat, or form of the body employed. This increased action has often a salutary effect, which is frequently felt through the whole frame. Torpor and paralysis of the nervous system often disappear, and neuralgia both of the neighbouring and even distant parts is removed. Atony and laxity of the muscular system vanish, and every part displays more energy and power.

The actual cautery may be applied in a variety of ways, viz., hot water, hot vapour, moxa, and heated iron. The first of these is a very ready means of causing vesications in some diseases. In phthisis pulmonalis, or consumption, where pain is often more relieved by vesication than any other means, placing a sponge in a wine-glass, and pouring boiling water on it, then suddenly inverting the glass over the part of the chest where the pain is felt, will cause immediate vesication, followed by speedy relief. The vapour of boiling water, as it issues from the spout of a kettle, is also a convenient method of applying heat in inflammations of the joints, as in gout, morbus coxarius, and other deep-seated diseases of the bones. As the red-hot iron is now seldom used, being confined to veterinary medicine, moxa affords the best substitute, and it is very convenient as any degree of intensity or rapidity of action can be given to it. [Moxa.]

The eschar which follows the application of the potential or actual cautery generally separates in a few days. The ulcer is then to be treated with different agents, according as it is wished to heal it or keep it open, as a farther means of counter-irritation.

ESCHEAT, from the Norman French word *eschet* or *echet*, chance or accident (a word derived from *escheoir*, the old French form of the verb *échoir*, "to fall"), is defined by Sir William Blackstone as an obstruction to the course of descent by some unforeseen contingency which consequently determines the tenure. In this case the land results back by a kind of reversion to the original grantor or lord of whom it is holden.

Escheat takes place when the tenant of lands dies intestate and without an heir: in such case the lands, if freehold, escheat to the king, or other lord of the fee; if copyhold, to the lord of the manor. Lands which have descended to the last tenant from a paternal or maternal ancestor, escheat, if there are no heirs on the part of that ancestor from whom the lands descended. Since the 1st day of January, 1834, there can be no escheat on failure of the whole blood, wherever there are persons of the half-blood capable of inheriting, under 3 and 4 Will. IV., c. 106.

If a bastard dies intestate and without issue, his lands escheat to the lord of whom they are held.

Escheat also takes place upon attainder for treason and murder, by means of which the blood is in law considered to be corrupted, and the attainted owner of lands rendered incapable of holding them himself, or transferring them by descent. In consequence of this extinction of heritable blood, the lands of such felons revest in the lord, except in cases of treason, when a superior law intervenes, and they become forfeited to the crown. Previously to the statute (3 & 4 William IV., c. 106) a person could not trace his descent through another person who had been attainted; but this may now be done, provided that other person shall have died before such descent shall have taken place. [Attainder.] And by the 4 & 5 William IV., c. 23, no property vested in any trustee or mortgagee shall escheat or be forfeited by reason of the attainder or conviction for any offence of such trustee or mortgagee, except so far as such trustee or mortgagee may have a beneficial interest in such property.

This doctrine of escheat consequent upon the commission of certain crimes is derived from the feudal law, by which a vassal was only permitted to hold real property upon condition of well demeaning himself.

The doctrine of escheats, with regard to extinct successions, seems to have been adopted in every civilised country, to avoid the confusion which would otherwise arise from the circumstance of any property becoming common; and the sovereign power, or those who claim under it, are consequently the ultimate heirs to every inheritance to which no other title can be found.

ESCHEATOR, an ancient officer, so called because his office was to look after escheats, wardships, and other casualties belonging to the crown.

There were at first only two escheators throughout England, one on this side and the other beyond the Trent; but in the reign of King Edward III. there was one appointed for every county, who was to continue in office for one year only. This office has long ceased to exist.

ESCROW. [Deed.]

ESCUAGE, or SCUTAGE, a pecuniary payment, by way of commutation for the knight-service, whereby the tenant was bound to follow his lord into the wars at his own charge. The term is derived from the Latin *scutum*, 'a shield.'

The personal attendance due by knight-service growing troublesome and inconvenient, the tenants found means of compounding for it, first by sending others in their stead, and in process of time by making a pecuniary satisfaction to the lords in lieu of it. This ultimately came to be levied by assessments, at so much for every knight's fee; and therefore this tenure was called *scutagium* in Latin, or *servitium scuti;* as being a pecuniary substitute for personal service. The first time it appears to have been taken was by Henry II., on his expedition to Toulouse; but it soon came to be so universal, that personal attendance fell into disuse. From this period, when our kings went to war, they levied scutages on their tenants, that is, on all the landholders of the kingdom, to defray their expenses and hire troops; and these assessments, in the time of Henry II., seem to have been made arbitrarily and at the king's pleasure. This prerogative being greatly abused by his successors, it became matter of national complaint, and King John was obliged to consent, by his *Magna Charta* (c. 12), that no scutage should be imposed without consent of parliament. This clause was omitted in Henry III.'s charter; where we only find (c. 37), that scutages should be taken as they were used to be taken in the time of Henry II.; that is, in a reasonable and moderate manner. Afterwards by 25 Edw. I. c. 5 & 6 and many subsequent statutes, it was enacted, that the king should take no aids or tasks but by the common assent of the realm. Hence it is held that scutage could not be levied but by consent of parliament, such scutages being indeed the groundwork of all succeeding subsidies, and of the land-tax of later times.

ESCULETIN. [Esculin.[

ESCULIC ACID. *Saponic Acid, Sapogenin.* By adding a little hydrochloric or sulphuric acid to a boiling solution of Saponin, a white substance is precipitated, to which M. Fremy gave the name esculic acid, and the formula $C_{52}H_{46}O_{24}$. According to Rochleder and Schwartz, it is identical with *quinovatic acid* ($C_{12}H_{10}O_4$), whilst M. Bolley terms it, *sapogenin*, and gives it the formula $C_{24}H_{18}O_{10}$.

Esculic acid presents the appearance of white granular tasteless crystals scarcely soluble even in boiling water, insoluble in ether, but easily soluble in alcohol. It forms salts with bases, and is transformed into a yellow resin by nitric acid.

ESCULIN. *Polychrome.* A neutral crystalline substance found in the bark of the horse-chestnut tree [Æsculus, in Nat. Hist. Div.], [Pavin]. The aqueous infusion of the bark is treated with excess of acetate of lead, and the filtered liquor, after removing excess of lead by sulphuretted hydrogen, evaporated till of a syrupy consistence; after a few days the esculin crystallises out, and may be purified by recrystallisation, first from dilute alcohol (sp. gr. ·940), and then from boiling water.

The formula of esculin, after drying in a water-oven, is $C_{42}H_{24}O_{26}$. It crystallises in small colourless needles, without odour, and of a bitter taste. It is very soluble in hot water, less so in alcohol, and but slightly soluble in ether or cold water. It fuses at 320° Fahr., at a higher temperature decomposes, emitting an odour of caramel, and yields a small quantity of a crystalline sublimate (*esculetin*).

Solutions of esculin are remarkable for their high fluorescent power, appearing of a deep blue colour by reflected light, while by transmitted light they are colourless. This property still obtains in a solution containing only one part of esculin to one and a half million parts of water.

Esculin is one of the so-called *glucosides*, that is, by the action of boiling dilute acids, or of the ferment emulsin, it splits up into glucose (grape sugar), and *esculetin*, according to the following equation:—

$$\underbrace{C_{42}H_{24}O_{26}}_{\text{Esculin.}} + 6HO = \underbrace{C_{18}H_6O_8}_{\text{Esculetin.}} + \underbrace{2C_{12}H_{12}O_{12}}_{\text{Glucose.}}$$

Esculetin is but slightly soluble in water or alcohol, but freely so in either, if boiling. It forms small acicular or micaceous crystals. Solutions of acetate of lead and of esculetin, yield a lemon-yellow precipitate, in which two of the six equivalents of hydrogen in esculetin are substituted by two equivalents of lead.

ESCUTCHEON or ESCOCHEON, the heraldic term for the shield, on which, under every variety of shape, arms are emblazoned. The word is derived from the French *écusson*, and that from the Latin *scutum*. The first representation of arms was, no doubt, as an ornament to the shield. The shield afterwards became the appropriate and legitimate instrument for displaying them; hence in sculpture and painting they were never separated; and when shields ceased to be employed, their form remained, and still continues to be the field on which coat-armour is invariably depicted. An *escutcheon of pretence* is the small shield in the centre of his own, on which a man carries the coat of his wife, if she is an heiress and he has issue by her. In this case the surviving issue will bear both coats quarterly.

ESENBECKINE. An alkaloid of uncertain composition, said to be contained in the bark of the *Esenbeckia febrifuga*.

ESOTERIC. [Exoteric.]

ESPALIER, a trellis for training fruit trees or bushes upon, instead of nailing them to walls.

In certain situations this kind of training is not only extremely neat, but possesses peculiar advantages: the trees are more fully exposed to the influence of light, less liable to be broken by high winds, and in small gardens in particular, where room is of great importance, and where a collection of the finer sorts of fruit is always desirable, it is found highly useful, both on account of the small space which the trees occupy, and because they will bear fruit much sooner than when allowed to grow in their natural form.

In France and other parts of the continent this kind of training is very much practised, and in the northern parts of England and in Scotland, where the borders of the kitchen-garden are frequently planted with flowers, in order to combine pleasure with utility, espaliers are trained along the back of the flower borders to prevent the vegetables being seen from the walks.

When the espalier is fastened to a wall, as is very common on the continent, peach and nectarine trees are frequently trained upon it; but where it is detached, as it is most commonly in Britain, apples and pears, and sometimes gooseberries, are the only fruits which are successfully cultivated in this way. Plums and cherries are occasionally so managed, but not so advantageously as the others.

When a common espalier is to be covered, the trees should be planted from 20 to 24 feet apart, which will allow the branches to grow 10 or 12 feet on each side; but as a considerable time would elapse before they would fill this space, a duplicate tree may be planted between each, and cut away as the others grow. Gooseberries, of course, require a small space; three or four feet from plant to plant is sufficient.

The training on espalier is very simple, and easily performed. When the trees are young, one shoot must be trained perpendicularly, and two others horizontally, one from each side; the two last must not be shortened, but the perpendicular shoot is to be shortened in the following year to three good buds, two of which are to form new side branches, and the other a leader as before; and so on every year until the trees have attained the desired size. The proper distance between the horizontal branches must depend upon the peculiar growth of the tree, but from six to nine inches is what is generally allowed. Trees are sometimes trained upon a double espalier, which has the advantage of giving two surfaces to train upon. It consists of two trellises instead of one, about two feet apart at the bottom, and approaching at the top.

The only kind of espalier worth notice, which differs from those now mentioned, is a table rail; this, the management of which is called table-training, consists of rails resembling tables, up the centre of which the tree is trained, and regularly spread over the surface. It is rarely employed, and has the essential fault of exposing the blossom so much to the effect of nocturnal radiation, that in this country a crop is rarely obtained from such espaliers.

The stakes which form the espalier are made of different materials, some of wood, others of wire and wood, and some of cast iron. The first of these is by far the most simple, and is composed of stakes, five or six feet in height, driven into the ground from one to two feet apart; along the top a bar, which is nailed to each, connects the whole together. It is of no use to have the stakes either so strong or so high when the trees are first planted, because they are not required, are unsightly, and will have to be renewed before the trees have attained their intended height; for this reason, stakes of a much weaker kind will at first answer quite as well. The wire and wood rail is formed by strong vertical wires, strained from two wooden horizontal rails, which are connected and held fast by wooden posts let into the ground. The iron rail is constructed upon the same plan as a common street railing.

The objection to all iron trellises is, that they cut and canker the trees; and when the cheapness of the wooden one is considered, besides the more natural appearance which it presents, it must undoubtedly have the preference.

The best wood for this purpose is young larch, the thinning of plantations.

ESPLANADE, the ground kept open between the fortifications of a citadel and those of a town to which it belongs. It is recommended by writers on fortification that this space should be about 300 fathoms broad, reckoning from the covered way of the citadel, that in the event of an attack on the latter the enemy may not construct batteries within breaching distance under the cover afforded by the buildings of the town. If however the ground should be built over, it would be advisable to clear it to that extent in case of a siege.

ESQUIRE (from the French, *Escuier*, or shield bearer) is the next title of dignity to that of knight. The esquire was the second in rank of the aspirants to chivalry, or knighthood, and had his name from carrying the shield of the knight, whose bachelor or apprentice in arms, he was. The gradations of this service, or apprenticeship to arms, were, page, esquire or bachelor, and knight, who, in his turn, after the formation of degrees of knighthood, was called a knight bachelor, as aspiring to the higher honours of chivalry. The esquire was a gentleman, and had the right of bearing arms on his escutcheon or shield; he had also the right of bearing a sword, which denoted nobility or chivalry, though it was not girded by the knightly belt; he had also a particular species of defensive armour, which was distinguished from the full panoply of the knight. So much for the esquire of chivalry, which order is only preserved in the almost obsolete esquires for the king's body, whom antiquaries have pronounced to be the king's esquires in chivalry (that is, his esquires, as being a knight), and in the esquires of knights of the Bath.

There was also another class, who may be called feudal esquires, and consisted of those tenants by knight's service who had a right to claim knighthood, but had never been dubbed. They were in Germany called *Ritters*, or knights, but were distinguished from the actual knights, who were called dubbed knights, or *Ritter Geschlagen*, and had many of the privileges of knighthood. This distinction still exists in many of the countries which formed part of the German Empire. In Hainault, Brabant, and other provinces of what was Austrian Flanders, the ancient untitled nobility, or gentry as they are called in England, to this day are styled collectively the *Ordre Equestre*, or knightly order. It also existed in England until James I. had prostituted the honour of knighthood, for Camden frequently speaks of knightly families (*familias equestres*, or *familias ordinis equestris*), where the heads of them were not, at the time, actual knights. Writers on precedence make mention of esquires by creation, with investiture of a silver collar or chain of *ss*, and silver spurs: but these seem to have been only the insignia of the esquires for the king's body, which being preserved in a family as heir looms, descended with the title of esquire to the eldest sons in succession. The sons of younger sons of dukes and marquesses, the younger sons of earls, viscounts, and barons, and their eldest sons, with the eldest sons of baronets, and of knights of all the orders, are all said to be esquires by birth, though their precedence, which differs widely, is regulated by the rank of their respective ancestors. Officers of the king's court and household, and of his navy and army, down to the captain inclusive, doctors of law, barristers, physicians, and Royal Academicians, are reputed esquires. A justice of the peace is only an esquire during the time that he is in the commission of the peace, but a sheriff of a county is an esquire for life. The general assumption of this title by those who are not, in strictness, entitled to it, has virtually destroyed it as a distinct title or dignity. The heads of many old families are, however, still deemed esquires by prescription.

ESSAYISTS, BRITISH. This title is customarily confined to a certain class of periodical writers upon subjects of general interest, as morals, criticism, manners, &c. The notion of a series of papers fit for general circulation, and not including news or politics, was originated by Steele and Addison in the 'Tatler.' [ADDISON, in BIOG. DIV.] The 'Freeholder,' 'Craftsman,' 'Freethinker,' &c., now almost forgotten, were rather political pamphlets than essays in this sense of the word; and an interval of thirty-five years elapsed from the end of the 'Spectator' to the successful revival of this style of writing by Dr. Johnson, in the 'Rambler,' in 1750. Its great popularity led to the establishment of a number of similar periodicals during the latter half of the 18th century, since which time they have again gone out of fashion. We give a list of those contained in Alexander Chalmers's collective edition of British Essayists, which includes some that have little claim to a place among the standard works of our language: with the names of the principal and most celebrated contributors to each:—

'Tatler'—Steele, Addison.
'Spectator'—Addison, Steele, Budgell, Pope, &c.
'Guardian'—Steele, Addison, Berkeley, Pope, Tickell, Gay, &c.
'Rambler'—Johnson, almost entirely.
'Adventurer'—Hawkesworth, Johnson, Joseph Warton, &c.
'World'—Moore, Lord Chesterfield, Horace Walpole, J. Warton, &c.
'Connoisseur'—G. Colman and Bonnel Thornton chiefly; Cowper a few.
'Idler'—Johnson; a few by Warton and others.
'Mirror'—Henry Mackenzie and others.
'Lounger'—The same.
'Observer'—Richard Cumberland, almost entirely.
'Olla Podrida'—Moore, &c.
'Microcosm'—Canning, Frere, Smith, &c.

ESSENCE is derived from the Latin *essentia*, a word which is used by Cicero and Quinctilian, and formed, not as is stated in Mr. Richardson's Dictionary, from *existentia*, but from *essens*, the analogous but obsolete participle of the verb *esse*, to be. The English word essence consequently signifies that which constitutes the being of a thing, or, in the words of Locke, that which makes it to be what it is. This term was the subject of many very subtle disquisitions and disputes among the scholastic logicians of the 14th, 15th, and 16th centuries; and the metaphysical notions of essence entertained by these logical doctors cannot be understood without reference to their discussions respecting the nature of universal ideas, as real or nominal, of abstraction, genus, species, differentia, substance, properties, accidents, &c., of all which particulars may be found in Smiglecii 'Logic. Disputat.'; Burgersdicii 'Logica;' Eustachii 'Logica;' Le Grand, 'Institut. Logic.'; Wallisii 'Logica'; and in many other logical and philosophical treatises cited in Johnson's 'Quæstiones Philosophicæ,' p. 168, &c. Some amusing instances of metaphysical sagacity concerning logical essence are exhibited in the scholastic work of Louis de Lesclache, 'La Philosophie, divisée in cinque Parties,' 1548.

"Il n'y a rien dans la substance qui ait moins d'essence que la substance; aussi il n'y a rien dans la substance qui soit moins substance que la substance," &c. In the 'Oxford Manual of Scholastic Logic,' by Dr. Aldrich, as expounded by Mr. Huyshe, it is taught, in accordance with the theory of the Nominalists, that essence is not really existent, but is merely a figment of imagination, and that the notion of it is resolvable into two parts; that which is common to other essences being called the *genus*, and that which is peculiar to one particular essence, distinguishing it from all others, and constituting it what it is, being called the *differentia*. The whole essence is called the species; that is, genus + differentia = species. The qualities joined to essence are also of two kinds; those which are joined necessarily are called *properties*, and those which are joined only contingently are called *accidents*. Hence the five predicables, or only possible parts of a thing which can be the objects of assertion:—1. Species or whole essence. 2. Genus, the common or material part of the essence. 3. Differentia, the peculiar or formal part of the essence. 4. Property or quality necessarily joined to the essence. 5. Accident, or quality contingently joined to the essence. The following statements collected from Locke's 'Essay,' book iii., c. 3 and 6, exhibit the principal points of his doctrine of essence. He considers essence to be of two kinds: 1. The real essence, which constitutes the insensible parts of a thing, and is wholly unknown to us. 2. The nominal essence, which depends on that which is real, and is the complex idea, for instance, of the properties of colour, weight, malleability, fixedness, fusibility, &c., expressed by the word gold; for nothing can be gold which has not the qualities conceived in the abstract idea to which this name is applied. In simple ideas (see book ii. c. 2), the real and nominal essence are identical, but in substances they are always different. Each of the distinct abstract ideas which men make and settle in their minds by giving them names, is a distinct essence; and the names which stand for such distinct ideas are the names of things essentially different. Thus, a circle is as essentially different from an oval as a sheep from a goat; the abstract idea which is the essence of one being impossible to be communicated to the other. As essences are nothing but the abstract complex ideas to each of which has been annexed a distinct and general name, and as of such ideas there are some which correspond to no reality in nature—for instance, those of mermaids, unicorns, &c.—it is evident that there are essences of things which have no existence. In considering essence with regard to the scholastic theory of genus and species, Locke observes that we classify things by their nominal essences, having no other measure of essence and species but our abstract general ideas or mental archetypes, without reference to which we cannot intelligibly speak of essential and specific difference. The doctrine of the immutability and ingenerable incorruptible nature of essences can be founded, says Locke, only on the relation between abstract ideas and the sounds by which they are signified; that is, on the fact that the same name retains the same signification, and also on the fact that, whatever may become of individuals, as Alexander and Bucephalus, the ideas of man and horse remain unaltered. Some of these positions, as that real essences are unknown, and that species are distinguished by essences merely nominal, are disputed in Green's 'Philosophy' and Lee's work against Locke. (See also many of the earlier scholastics; and for an exposition of the doctrine of essence, according to the transcendental theory, see Kant's 'Kritik der reinen Vernunft' and Wirgman's 'Logic and Metaphysics' in the 'Encyclopædia Londinensis.') Substance, as distinguished from essence, is understood to mean all the essential, with the accidental qualities; and essence (genus and differentia, or common and proper) the essential qualities alone, that is, the pure substance, or metaphysical substratum. The Greek word *ousia* (*οὐσία*) has many significations applicable to the individual, genus, species, and subject (Aristotle, 'Metaphys.' l. 6, c. 3); on which it is remarked by Roy Collard 'Essai sur la Psychologie,' 1826, p. 149, 246), that while the Latin and all modern languages have two distinct expressions for essence and substance, it is surprising that the Greek, which is otherwise so rich, had only one name (*οὐσία*) for these two ideas. The word *ὑπόστασις*, *hypóstasis* (substance), was subsequently employed, but with similar duplicity and confusion. Hence arose many of the Trinitarian controversies, or rather logomachies, which embroiled the first ages of the church; for Athanasius, Epiphanius, and most of the other Greek fathers understood *πρόσωπον*, person or mode of being, as meaning the same thing as *ὑπόστασις*, substance; and Sabellius, Arius, Nestorius, and Eutyches understood *ὑπόστασις*, as signifying the same thing as *οὐσία*, that is, essence or nature. So that Sabellius said, there is one essence or nature in God, *therefore* one substance or person. There are three substances or persons in God, said Arius, *therefore* three essences or natures. There are two essences or natures in Christ, said Nestorius, *therefore* two substances or persons. There is but one substance or person in Christ, said Eutyches, *therefore* but one essence] or nature. The essay on the difference between *οὐσία* and *ὑπόστασις*, essence and substance, which is often attributed to St. Gregory, appears to belong rather to St. Basil; at least it is contained in his 43rd epistle. The epithet *essential* denotes those indispensable qualities in a thing, without which it could not be what it is; and the name *essentials*, as the essentials of logic, signifies those parts alone which are valid for general or particular uses.

ESSENCES. In various departments of manufactures, as well as in pharmacy and perfumery, liquids are largely sold under the name of essences. Originally the word was employed to denote the active and characteristic portion of any substance, or that on which its special properties mostly depend; but in the present day the term is very loosely applied. Sometimes essence is equivalent to *fluid extract*, sometimes to *volatile oil*, at other times to *strong solution*, to *concentrated preparation*, to *infusion*, to *decoction*, and to *tincture*. The essences of the pharmaceutist consist, in some instances, of the active ingredient of the plant digested in spirit; in others, of a solution of the essential oil in spirit; in others, of the volatile or aromatic element obtained by distillation. Among the large number of essences now made and sold, a few may be named useful in the arts, besides those pertaining more especially to medicine. Essence of allspice or pimento is used to make pimento-water, and as a flavouring ingredient in cookery and confectionery. Essence of almonds is used to impart an agreeable flavour and aroma to wine, cordials, perfumery, and pastry; to prepare almond-water and other liquids; to give a sherry flavour to Cape wine, and sometimes to sophisticate sherry itself. Essence of ambergris is a powerful ingredient in many perfumes, and is also added in the preparation of sweet-scented wines and spirits. Essence of aniseed is used to flavour liquors, and to make aniseed-water. Essence of cardamom is a powerful ingredient for flavouring cordials and pastry. Essence of cognac, made from brandy oil and spirit, is used to give to British spirit an imitative flavour of real brandy. Essence of grape is used to flavour brandy. Essence of hop is used occasionally to add a stomachic bitter to a glassful of ale or beer. A so-called essence or extract of hop is, however, not unknown to brewers as an adulterant, consisting of bitter preparations of quassia, gentian, camomile, aloes, or wormwood, not containing a particle of hop. Essence of ratafia is employed in the preparation of the liquors called ratafia and noyeau. Essence of rosemary, besides its use as a perfume, is employed in making rosemary-water. Essence of spruce is used in making spruce-beer. There are numerous other essences employed to impart flavour or odour to beverages, perfumery, or pastry; among which may be named the essences of apple, bergamot, carraway, cedrat, celery, cinnamon, cloves, jasmine, jonquil, lavender, lemon, lemon-peel, myrtle, nutmeg, orange, orange-peel, patchouli, pear, peppermint, pine-apple, rondeletia, rose, vanilla, verbena, violet, &c. There are also certain essences, so-called, obtained from animal substances, and applied to various purposes: of which a few may here be briefly noticed. Essence of anchovies consists of the substance of the fish, when the bones have been removed, pulped and sifted, and simmered for a few minutes in a liquid in which the bones have been boiled, and to which salt, flour, and vinegar are added. Essence of anchovies, improperly so named, is sometimes made from pickled sprats or young pilchards, mixed with the drainings of anchovy barrels or with herring liquor; it is coloured with Venetian red or Armenian bole, which is not only an adulterant, but an injurious one. Essence of beef consists of the nutritive portions of the meat, concentrated into a liquid by decoction and infusion, and preserved in well-closed bottles. Essence of civet and essence of musk, prepared from parts of certain animals, take rank among the list of perfumes. Essence d'Orient, prepared from a pearly-looking substance found at the base of the scales of the blay or bleak fish, is employed as an inner coating for glass bubbles or beads, to make artificial pearls. Essence of turtle is a miscalled preparation, in which, by combining essence of anchovies with many other substances, a liquid is produced to impart a flavour like that of turtle to soups and gravies.

ESSENES (sometimes called Hessenes), one of the three great sects into which the Jews were divided in the time of Christ. They are not mentioned in the New Testament; but it has been conjectured that they are alluded to in Matt. xix. 12, Col. ii. 18, 23. Many particulars concerning the customs and religious opinions of this sect are given by Josephus and Philo. Their statements differ in several points; but those of Josephus appear worthy of more credit, since he had in his youth passed some time among the Essenes. ('Antiquities of the Jews.')

The Essenes generally lived at a distance from large towns, in communities which bore a great resemblance to the monkish societies of later times. They employed themselves in agriculture, and had no slaves. They had all things in common, ate at a common table, and were exceedingly abstemious, never partaking of food before sunset. They were clothed in white garments, abstained from wine, and generally led a life of celibacy. They sent gifts to the Temple, but never offered any sacrifices there. They were divided into four classes, according to the time of their initiation. They admitted no one to their society till after a probation of three years; those who were admitted had to take solemn oaths that they would worship and serve God, and be just towards their fellow creatures; that they would love and speak the truth, and that they would never disclose the mysteries of the sect. The Essenes were exemplary in their religious duties, and were particularly distinguished by their rigid observance of the Sabbath-day. They believed in the immortality of the soul, but not in the resurrection of the body, and maintained the absolute predestination of all events; they held the Scriptures in the greatest reverence, but considered them as mystic writings, and explained them allegorically. They also appear to have possessed sacred books, which explained the peculiar doctrines and practices of their sect. (Philo, 'De Vita Contempl.,' vol. ii., p. 475.)

The origin of this sect is uncertain. Some writers consider them the same as the Assidians, or Chasidim, who are mentioned in 1 Macc. ii. 42; vii. 13. It would appear from the account of Pliny ('Nat. Hist.' v. 17) that their principal society was on the western side of the Dead Sea; and that from this society other smaller ones afterwards proceeded, and spread themselves over Palestine, Syria, and Egypt. Their numbers were never considerable: according to Philo and Josephus, there were only 4000 in Palestine.

The Essenes of Egypt were divided into two sects: the practical Essenes, whose manner of life was the same as the Essenes of Palestine; and the contemplative Essenes, who were also called Therapeutæ. Both sects maintained the same doctrines, but the latter was distinguished by a more rigid mode of life.

From a passage in Eusebius ('Hist. Eccles.' ii. 17), it has been argued by Bellarmine, Baronius, and other Roman Catholic writers, that the Therapeutæ were Christian monks formed into a society by St. Mark, who was the founder of the Christian church at Alexandria. But it is evident from the account of Philo, that the Therapeutæ were not Christians, but Jews.

It has been supposed, with considerable probability, that the early Christians derived many of their customs and opinions from the Essenes. Mr. Taylor, the editor of Calmet's 'Dictionary to the Bible,' gives many reasons for believing that John the Baptist belonged to this sect.

ESSENTIAL OILS, the odorous principles of plants, called also *Volatile Oils*, to distinguish them from the non-volatile or fixed oils. [FIXED OILS.] The present article will be devoted to a consideration of their sources, methods of production, uses, and general physical and chemical properties, together with an alphabetical list of those known up to the present time, including the specific characters of each, or references to other articles in this Cyclopædia where those characters are more fully detailed.

Sources.—Essential oils are not peculiar to any particular part of plants. They may reside in the root, stem, leaf, flower, fruit, or seed. They are generally contained in special cavities called receptacles of secretion. These cavitites are frequently larger than the surrounding cells, and indeed may often be seen with the naked eye. The dotted appearance of the rind of the orange and lemon, and of the leaves of the myrtle and St. John's wort [HYPERICUM, in NAT. HIST. DIV.] is due to the presence of numerous oil cavities. The cellular tissue forming the walls of the cavities is in many cases so compact that the plant may be dried and kept for several years without much of the oil being dissipated.

In nearly all instances the essential oils exist ready formed in plants. In the bitter almond and black pepper, however, contact with water is necessary to the production of the oil. Some other plants also, as milfoil, plantain, nettle, and centaury, which naturally have little or no odour, appear to undergo, when sprinkled with water, a kind of fermentation by which abundance of essential oil is produced. Finally, during the putrefaction of many vegetable matters, peculiar essential oils are generated.

Methods of Production.—In nearly all cases essential oils are obtained by a process of distillation. The plant, or that part of it from which the oil is to be extracted, is usually macerated for a few hours with four or five times its weight of water in a still furnished with a false bottom. Heat being applied, and the contents of the still brought into an active state of ebullition, the essential oil is volatilised along with the steam, and the vapours being condensed in any suitable way [CONDENSER] will, if the oil is present in sufficient quantity, separate into two portions, one a saturated solution of the oil in water, and the other a layer of the essential oil itself. The oil being collected by any suitable contrivance, the water should be occasionally returned to the still, and the distillation continued until the oil ceases to come over. The object of having a false bottom to the apparatus is to prevent portions of the plant from coming into immediate contact with the heated surface of the still, thus avoiding an unpleasant tarry taste and odour that would be communicated to the oil by volatile substances evolved from the overheated vegetable matter. The same end is arrived at by enclosing the ingredients acted upon in a bag, and so suspending the whole that it shall not touch any portion of the still. Even more advantageous is a plan now frequently adopted, of blowing steam from a perforated coil pipe through the materials to be acted upon, and condensing the vapours as before.

The water used in the above process dissolves a small portion of the oils, forming solutions that are used in medicine as vehicles for active preparations. Where it is required that these waters should be preserved, every trace of the excess of oil should be carefully removed; in some cases, redistillation of the water without the presence of the herb is beneficial.

If the water is not needed, the oil contained in it may be recovered by adding chloride of sodium to saturation, essential oils being but slightly soluble in the solution thus formed. Or the water may be agitated with ether, which will dissolve out the oil; the oil is then readily obtained by distilling off the ether.

In a few instances the essential oil of a plant cannot be extracted by distillation, on account of the injurious action of heat upon it, or because of its smallness in quantity. In that case, the substances to be operated upon may be placed in layers alternate with cloths saturated with an inodorous fixed oil, such as oil of poppies, and the cloths after a time submitted to strong pressure. The essential oil will then be found to have dissolved in the fixed oil, to which it will communicate its characteristic odour, and from which it may, if necessary, be separated by agitation with alcohol.

The oils of lemon and orange may be extracted by simple pressure of the rind of the fruit.

Uses.—The most extensive use of essential oils is in the fabrication of perfumes. Considerable quantities are also used in medicine, as topical or gastro-intestinal stimulants.

On account of the essential oil they contain, plants, or certain parts of them, are used to flavour liqueurs, confectionery, salads, savoury dishes, soups, &c.

Physical Properties.—The colour of essential oils is variable. The portions first obtained in the process of distillation are sometimes quite colourless, the later portions yellow or brown. These portions are however generally mixed together for commerce, so that essential oils are seldom seen without colour. Moreover nearly all the essential oils darken in colour on exposure to light and air. A few of them are green, and two or three of a blue colour. The essential oils have characteristic odours more powerful, but seldom as pleasant as that of the plants from which they are obtained. Their taste is hot and irritating. They have not the well-known unctuous feel that the fats and fixed oils possess when rubbed between the fingers, but on the contrary, are rough and harsh. They are nearly all lighter than water; a few however are heavier. The temperature at which the essential oils assume, on the one hand, the solid state, and on the other, the state of vapour, is very inconstant. This is explained by the fact that they are usually mixtures in variable proportions of a pure hydrocarbon, or *elæopten*, with an oxygenated hydrocarbon, or *stearopten*, the former commonly boiling at about 320° Fahr., the latter between 390° and 465°. Some of the essential oils are solid at temperatures below 60° Fahr., others require to be cooled several degrees below the freezing point of water before congelation occurs. The elæopten may generally be roughly separated from the stearopten by cooling the oil gradually. In the air the essential oils burn with a bright flame accompanied with much soot.

Chemical Properties.—Exposed to the air, essential oils absorb oxygen, and are slowly converted into resinous matters. During this process carbonic acid is sometimes evolved. Light favours the action. Essential oils are soluble in ether and alcohol, and to a slight extent in water. They are not soluble in caustic alkalies, and, with the exception of clove, pimento, and cinnamon-leaf oils, are not capable of saponification. They dissolve fixed oils, fats, and resins, with which they are not unfrequently adulterated; such fraud may, however, be easily detected by exposing a drop of the suspected oils on blotting-paper; if pure it will evaporate in a short time without leaving any stain; if mixed with either of the above substances, a greasy stain will be left on the paper. On passing the vapour of an essential oil over fused hydrate of potash, it is usually oxidised to an acid body that combines with the alkali, hydrogen gas being at the same time evolved. Chlorine, bromine, and iodine act upon and replace hydrogen in most of the essential oils. Nitric acid rapidly oxidises them.

Composition.—The ultimate chemical composition of essential oils is carbon, hydrogen, oxygen, and sometimes sulphur. In chemical and pharmaceutical treatises they will usually be found arranged in three divisions, according to their proximate composition:—1. Pure hydrocarbons; 2. oxidised hydrocarbons; 3. oils containing sulphur. 1. The pure hydrocarbons are nearly all isomeric and metameric, their molecule being represented by $C_{20}\,H_{16}$. Such are termed *camphogens* or *terebenes*, oil of turpentine being one of the members. Equal weights yield equal volumes of vapour; the specific gravity of them all is about ·860, and their boiling points range near 320° Fahr. They all absorb hydrochloric acid gas forming with it *artificial camphors* [TURPENTINE], and combine with water, forming solid bodies still more closely resembling camphor. Exposed to the air, they absorb oxygen, and are converted into resins. A few of the pure hydrocarbons have a composition differing from $C_{20}\,H_{16}$. 2. Oxidised hydrocarbons. Some of these are solid, forming the so-called *camphors* or *stearoptens* [CAMPHOR]. Others present the characters of an aldehyde, an alcohol, or an acid. The aldehydes, or hydrides as they are sometimes called, combine and form crystalline compounds with the bisulphites of the alkalies. 3. Oils containing sulphur. The members of this division are compounds of the radical ALLYL.

Tests for ascertaining the purity of the principal essential oils will be found described under the respective names of the latter. The necessary experiments, however, belong to the higher branches of pharmaceutical chemistry, and for this reason: that expensive oils are usually sophisticated with cheap ones, and from the great similarity that exists between many of them, both in physical and chemical properties, it necessarily follows that the detection of such adulterations is difficult. See 'Tests of the purity and adulteration of the volatile oils,' in 'Jahrb. für praktische Pharm., Juli. 1849,' and 'Pharmaceutical Journal,' vol. ix., old series, p. 575–580.

Essential oil of achillea, is obtained from the plant *yarrow*, or *milfoil*. [ACHILLEA, in NAT. HIST. DIV.] It is of a beautiful blue colour.

Essential oil of alliaria. The *alliaria officinalis* [ERYSIMUM, in NAT.

Hist. Div.] furnishes by distillation three essential oils. That from the root, before the leaves are developed, presents all the characters of sulphocyanide of allyl. [Mustard, Oil of.] That from the leaves is sulphide of allyl. [Garlic, Oil of.] The essential oil from the seed is sulphocyanide of allyl alone, or a mixture of that substance with sulphide of allyl.

Essential oil of almonds. [Benzoyl, Hydride of.]

Essential oil of allspice. See *Essential oil of pimento.*

Essential oil of amber. A product of the dry distillation of Amber. It is a mixture of several hydrocarbons analogous to oil of turpentine. Copal resin, and the resin of the dammar pine are frequently substituted for amber in the preparation of this oil.

Essential oil of anise is solid at temperatures below 50° Fahr. It contains one-fifth of its weight of a hydrocarbon analogous to oil of turpentine. The remaining four-fifths is a solid body of sp. gr. 1·014, melting point 65° Fahr., boiling point 432°. Its composition is $C_{20}H_{12}O_2$. [Anisic acid; Anisöin.] [Pimpinella, in Nat. Hist. Div.]

Essential oil of arnica. The root and flowers are said to yield two different oils. That from the flowers is blue.

Essential oil of artemisia. See *Essential oil of wormwood.*

Essential oil of asarabacca. This oil is composed of Asarone, and a liquid essential oil of yellow colour, acrid taste, and odour resembling valerian. [Asarum, in Nat. Hist. Div.]

Essential oil of asafœtida contains a compound of allyl, richer in sulphur than the sulphide of allyl. [Asafœtida.]

Essential oil of athamanta. See *Essential oil of peucedanum.*

Essential oil of balm, is of a pale yellow colour. Sp. gr. 0·975. [Melissa, in Nat. Hist. Div.]

Essential oil of balsam of Peru. This balsam owes its fragrance to Cinnamein. [Balsam *of Peru.*] [Myrospermum *Peruiferum,* in Nat. Hist. Div.]

Essential oil of basil. Sweet basil [Ocymum, in Nat. Hist. Div.] yields an oil containing a solid crystalline body resembling hydrate of oil of turpentine.

Essential oil of bays. See *Essential oil of laurel-berries.*

Essential oil of bergamot. [Bergamot, Essence of.]

Essential oil of birch is obtained by distillation of birch tar. It is a mixture of several oils; one of them is a hydrocarbon, $C_{20}H_{16}$. The odour of Russia leather is generally owing to this essential oil.

Essential oil of buchu is obtained by distillation with water from buchu leaves. Its colour is yellowish-brown. [Buchu.] [Diosma, in Nat. Hist. Div.]

Essential oil of cajuput. [Cajuput oil.]

Essential oil of camomile. Under this name there occur three different oils. First, that obtained from the true camomile plant. [Anthemis, in Nat. Hist. Div.] This is the oil that should be used in medicine, being the one indicated in the pharmacopœia. When first prepared it has a light green colour, but on exposure to air and light it becomes after a time yellow, and finally brown. It is composed of a hydrocarbon isomeric with oil of turpentine, and an oxidised portion, which Gerhardt ('Traité de Chimie organique,' tome ii. p. 445,) regards as the hydride of angelyl. Heated cautiously with caustic potash, the hydrocarbon is volatilised, and angelate of potash formed. A higher temperature decomposes the angelate of potash. [Angelic Acid.] A second oil of camomile is obtained from the wild camomile. [Matricaria, in Nat. Hist. Div.] It is prepared to a considerable extent in Germany, and is called in France essence of blue camomile. It is of a deep blue colour, and at common temperatures has the consistence of cream. The third oil is obtained from feverfew [Pyrethrum, in Nat. Hist. Div.], a plant closely allied to the camomile, and formerly named *matricaria*; hence the reason of its being confounded with oil of camomile. It is composed of a hydrocarbon and an oxygenised portion which hold in solution a camphor, differing but slightly from laurel camphor. [Camphor.]

Essential oil of candy-tuft, has the characters of sulphocyanide of allyl.

Essential oil of caoutchouc. [Caoutchin.]

Essential oil of capivi. Obtained by distilling balsam of capivi with water. [Balsam, *capivi.*] It is isomeric with oil of turpentine, but the hydrocarbon appears to be in a more condensed state, having the formula $C_{30}H_{24}$. Sp. gr. 878. Boiling point 500° Fahr.

Essential oil of cardamoms. [Cardamom, *essential oil of.*]

Essential oil of caraway. [Caraway, *oil of.*]

Essential oil of cascarilla is obtained by distillation with water. It has not been fully examined.

Essential oil of cassia, is, chemically, the same as *essential oil of cinnamon.*

Essential oil of cedarwood. [Cedarwood, *oil of.*]

Essential oil of cedrat. Another name for the *essential oil of citron-peel.*

Essential oil of celery is obtained from the seeds of the common celery. [Celery and Apium, in Nat. Hist. Div.] It contains a hydrocarbon ($C_{20}H_{16}$) that boils at 320° Fahr., and an oxygenised portion, the composition of which has not been satisfactorily established. The solution of the oil in spirit, made by digesting the seeds, is used as a flavouring essence.

Essential oil of chenopodium is used in the United States under the name of *wormseed oil.* It is obtained by distillation with water from the *Chenopodium anthelminticum.* It has a disagreeable odour, and yellow colour, sp. gr. ·98.

Essential oil of cherry laurel is very similar to essential of bitter almonds, containing hydrocyanic acid and hydride of benzoyl. [Benzoyl, *hydride of.*]

Essential oil of chervil. [Scandix and Anthriscus, Nat. Hist. Div.] It has not yet been chemically examined. [Chervil.]

Essential oil of cinchona. Trommsdorff obtained, by distilling 20 lbs. of cinchona bark with water, two grains of an essential oil having the odour of the bark and an acrid taste.

Essential oil of cinnamon. [Cinnamon, *oil of.*]

Essential oil of cinnamon-leaf. Obtained in Ceylon. The leaves are macerated in sea-water and the whole distilled. It is similar in composition and properties to oil of cloves. [Caryophyllic acid.]

Essential oil of citron-peel differs but slightly in composition and properties from essential oil of lemons. It has, however, an odour peculiar to itself, though the delicacy of the odour depends somewhat upon the part of the distillatory process at which it is taken. [Lemons, *oil of.*] [Citrus *medica,* in Nat. Hist. Div.]

Essential oil of citron-flowers is amber-coloured and slightly fragrant. Sixty pounds of flowers yield one ounce of oil.

Essential oil of citronelle. See *Essential oil of lemon-grass.*

Essential oil of cloves. [Caryophyllus; Caryophyllic Acid.]

Essential oil of coriander. Sp. gr. 0·872. Almost colourless. Possesses in a high degree the odour and taste of the plant. Boiling point about 302° Fahr. Its composition seems to be that of a hydrate of oil of turpentine ($C_{20}H_{16}+2HO$), but it needs farther examination. [Coriandrum *sativum,* in Nat. Hist. Div.]

Essential oil of cress. Yellow colour. Heavier than water. It contains sulphur, and is probably, like other essential oils from the natural order Cruciferæ, a compound of the radical Allyl. [Lepidium, in Nat. Hist. Div.]

Essential oil of cubebs. Cubebs [Piper *cubeba,* in Nat. Hist. Div.] contain 10·5 per cent. of a colourless essential oil having a camphrous taste and aromatic odour. It is generally more or less viscous. Sp. gr. 0·929. Boiling point a little below 500° Fahr. It contains the same hydrocarbon as essential oil of capivi. Cubebs also contain a solid camphor, a hydrate of the oil ($C_{30}H_{24}+2HO$). The camphor is also formed on rectifying oil of cubebs with water. It fuses at 154° Fahr., boils at 302°, is insoluble in water, but soluble in alcohol, ether, and the essential oils. [Cubebene.]

Essential oil of cummin. [Cymole; Cuminic acid; and Cuminum and Cyminum, in Nat. Hist. Div.]

Essential oil of dahlia. The tubercles of *Dahlia pinnata* furnish an essential oil, lighter than water. In the air it soon resinifies, and in water it after a time deposits crystals which appear to be benzoic acid.

Essential oil of dipterocarpus. Obtained on distilling *wood oil* with water. Wood oil is the resinous juice of several trees of the genus *Dipterocarpus.* [Dipterocarpus, in Nat. Hist. Div.] It contains about 60 per cent. of an essential oil of sp. gr. 0·928, boiling point 491° Fahr.

Essential oil of elder-flowers. [Sambucus, in Nat. Hist. Div.] Exists in very small quantity. Has a butyraceous consistence.

Essential oil of elemi, is contained in the resin [Amyridaceæ, in Nat. Hist. Div.] to the extent of from 7 to 14 per cent. Sp. gr. 0·850. Boiling point 345° Fahr. Its composition and vapour density are the same as oil of turpentine.

Essential oil of erysimum. See *Essential oil of alliaria.*

Essential oil of fennel differs in odour, but is composed of the same proximate constituents as *essential oil of aniseed.* [Fœniculum, in Nat. Hist. Div.]

Essential oil of galbanum. [Galbanum, in Nat. Hist. Div.] Obtained on distilling the gum-resin with water. Colourless, limpid, sp. gr. 0·912.

Essential oil of garlic. [Garlic, *Oil of.*]

Essential oil of gaultheria. See *Essential oil of wintergreen.* [Gaultheria, in Nat. Hist. Div.]

Essential oil of gentian may be procured from the root by distillation with water. It exists only in small quantity. It is lighter than water, and has the consistence of butter. [Gentiana *lutea,* Nat. Hist. Div.]

Essential oil of geranium. Several species of Pelargonium furnish a small quantity of essential oil, on distillation with water. This is true oil of geranium. For the commercial oil of geranium see *Essential oil of grass.* [Pelargonium, in Nat. Hist. Div.]

Essential oil of ginger. Sp. gr. 0·893. Boiling point 475° Fahr. A mixture of the hydrates of a hydrocarbon isomeric with oil of turpentine.

Essential oil of grain. The hydrated oxide of amyl. [Amyl.]

Essential oil of grass, or briefly *grass oil,* is the product of *Andropogon calamus aromaticus,* nat. ord. *gramineæ.* It is known in commerce as *oil of geranium,* is used in perfumery, and in the fabrication and falsification of attar of roses. It contains a hydrocarbon ($C_{20}H_{16}$), and an oxidised resinous portion.

Essential oil of hemlock has an acrid taste, and the peculiar odour of the plant. It is not poisonous. [Conium, in Nat. Hist. Div.]

Essential oil of hops contains the hydrocarbon, $C_{20}H_{10}$, along with valerole ($C_{12}H_{10}O_2$) [VALEROLE]. Exposed to the air it soon becomes resinified.

Essential oil of horsemint. [THYMENE; THYMOL.] [MENTHA *sylvestris*, in NAT. HIST. DIV.]

Essential oil of horse-radish. Sulpho-cyanide of allyl. [MUSTARD, OIL OF.] [COCHLEARIA *armoracia*, in NAT. HIST. DIV.]

Essential oil of hyssop has not been thoroughly examined. It is lighter than water.

Essential oil of india-rubber. [CAOUTCHIN.]

Essential oil of jasmin, generally obtained by placing jasmine flowers between layers of wool soaked in olive oil, and afterwards pressing out the oil. It may be separated from the fixed oil by agitation with spirit. At 32° Fahr. it deposits a crystalline stearopten.

Essential oil of juniper fruit. Boiling point 320° Fahr. It seems to be almost identical with oil of turpentine, but possesses less energetic lævo-rotation of a polarised ray of light. [JUNIPERUS *communis*, in NAT. HIST. DIV.]

Essential oil of laurel, or *laurel turpentine.* Isomeric with oil of turpentine. It is uncertain from what tree it is obtained. It is imported from Demerara. Sp. gr. at 56° Fahr. 0·8645.

Essential oil of laurel-berries, or *oil of sweet bay.* Obtained from the berries [LAURUS *nobilis*, in NAT. HIST. DIV.] by distillation with water. Pale yellow, transparent. Contains two isomeric oils ($C_{20}H_{16}O$). Sp. gr. of one 0·857, of the other 0·885.

Essential oil of lavender contains, in variable proportions, a crystalline matter resembling common camphor. The liquid portion appears to be isomeric with oil of turpentine. [LAVANDULA *angustifolia*, NAT. HIST. DIV.

Essential oil of lemon-grass, Essential oil of citronella, Essential oil of verbena. Obtained on distilling the grass *Andropogon citratum* with water. The plant is a native of India and Ceylon, but the oil is much used in this country for perfumery.

Essential oil of lemon-peel. [LEMON, *Essential oil of.*]

Essential oil of lemon-thyme. [THYMUS, in NAT. HIST. DIV.] Contains THYMENE and THYMOL.

Essential oil of lettuce. Lactucarium, the inspissated milky juice of the lettuce, furnishes on distillation with water an essential oil that has not been accurately examined.

Essential oil of mace. Obtained by distilling with water the arillus of the nutmeg. [MYRISTICA, in NAT. HIST. DIV.] It is at first colourless, but becomes yellow after a time. Its composition and use are similar to those of *Essential oil of nutmeg.*

Essential oil of male fern. On distilling the oil of male fern, obtained by digesting the plant in ether, a small quantity of a volatile oil is obtained.

Essential oil of marjoram. Sweet marjoram [ORIGANUM *marjorana*, in NAT. HIST. DIV.] contains an oil, differing in odour, but otherwise the same as that obtained from the common marjoram [ORIGANUM *vulgare*, NAT. HIST. DIV.] or origanum. One hundred pounds of the former herb yields about four ounces of oil, while the same weight of the latter herb yields double that quantity. This essential oil is composed of a hydrocarbon having the composition of oil of turpentine, and a hard colourless stearopten without odour and heavier than water.

Essential oil of masterwort, is a mixture of a terebene with an oxygenised portion. Distilled with water it gives an oil having the odour of essential oil of rosemary, and exactly the composition of oil of turpentine. [IMPERATORIA *ostruthium*, in NAT. HIST. DIV.]

Essential oil of meadow sweet. See *Essential oil of spiræa.*

Essential oil of milfoil. See *Essential oil of achillea.*

Essential oil of mustard. [MUSTARD, OIL OF.]

Essential oil of myrrh. Myrrh [BALSAMODENDRON, in NAT. HIST. DIV.] contains two and a half per cent. of an essential oil having the odour and taste of the resin. In contact with air it soon resinifies.

Essential oil of myrtle. Obtained in the usual way from the flowers and leaves of the plant, 100 lbs. yielding an average of about three ounces. [MYRTUS *communis*, in NAT. HIST. DIV.]

Essential oil of neroli. See *Essential oil of orange-flower.*

Essential oil of nutmeg. Obtained by distilling nutmegs [MYRISTICA, in NAT. HIST. DIV.] with water. It has an average sp. gr. of 0·92. It is colourless, and has the characteristic odour and taste of the nutmeg. It is composed of a hydrocarbon, lighter than water, and an oxygenised portion heavier than water. It contains in solution more or less of a stearopten, the melting point of which is 212° Fahr., and subliming point 234° Fahr.

Essential oil of olibanum. The gum resin olibanum [BOSWELLIA, in NAT. HIST. DIV.] yields about four per cent. of a colourless essential oil, having somewhat of the odour of oil of turpentine, but more agreeable. Its density is 0·866.

Essential oil of onion contains sulphur, and is probably identical with oil of garlic [GARLIC, OIL OF.]

Essential oil of orange-flower. Oil of neroli. Obtained by distilling the flowers with water. It is at first colourless but on exposure to light soon becomes red. It appears to be composed of two oils, one of which has an extremely pleasant odour, and is unusually soluble in water, the other unusually insoluble in water.

Essential oil of orange-leaf is obtained from the leaves of the bitter and sweet orange. It is met with in commerce under the name of *essence de petit grain.* Except in odour, it probably differs but little from the oil obtained from the rind of the fruit.

Essential oil of orange-peel has a peculiar odour, but in chemical composition, vapour-density, &c., it is identical with essential oil of lemon. [LEMON, *essential oil of*].

Essential oil of origanum. See *Essential oil of marjoram.*

Essential oil of parsley. Procured from the seeds [PETROSELINUM, in NAT. HIST. DIV.] It contains a hydrocarbon, isomeric with oil of turpentine, the boiling point of which is 320° Fahr., and a resinous portion containing oxygen.

Essential oil of partridge-berry. See *Essential oil of wintergreen.*

Essential oil of pennyroyal. This oil has a boiling point between 360° Fahr. and 370° Fahr. Its chemical composition seems to be the same as that of laurel camphor ($C_{20}H_{16}O_2$). It is present in the herb [MENTHA *Pulegium*, in NAT. HIST. DIV.] to the extent of about one per cent. Its sp. gr. is about 0·925.

Essential oil of pepper (white or black). Pepper owes its pungency to an essential oil having the same composition as oil of turpentine. Boiling point, 333° Fahr. Sp. gr., 0·864. Vapour-density, 4·73. The oil absorbs hydrochloric acid gas, and gives with it a crystalline camphor. [PIPER *nigrum*, in NAT. HIST. DIV.]

Essential oil of peppermint. [PEPPERMINT, *Essential oil of.*]

Essential oil of petit grain. See *Essential oil of orange-leaf.*

Essential oil of peucedanum. The fresh leaves [PEUCEDANUM *Oreoselinum*, in NAT. HIST. DIV.] contains an essential oil somewhat resembling that of juniper. Boiling point, 325° Fahr. Sp. gr., 0·843. It contains a hydrocarbon similar to oil of turpentine, and a small quantity of an oxidised portion.

Essential oil of pimento or *allspice.* [CARYOPHYLLIC ACID.]

Essential oil of pimpernel. The root of the common burnet [SANGUISORBA, in NAT. HIST. DIV.] furnishes a blue-coloured essential oil.

Essential oil of pine-apple is the butyrate of oxide of ethyl or butyric ether. [BUTYRIC ACID.]

Essential oil of poplar. Obtained on distilling with water the non-expanded flowers. [POPULUS *nigra*, in NAT. HIST. DIV.] It is colourless, of an agreeable odour, and heavier than water.

Essential oil of ptychotis ajowan [PTYCHOTIS, in NAT. HIST. DIV.] is obtained from the seeds, which contain between five and six per cent. It is composed of a hydrocarbon isomeric with oil of turpentine, and a stearopten that crystallises in beautiful oblique or rhombohedral crystals. On exposing the oil to the air in a shallow vessel these crystals may be obtained of considerable size. They are very similar, if not identical, with THYMOL. The Ptychotis is well known in India as an aromatic under the name of *ajowan* or *ajwain.*

Essential oil of radish. The seeds of the common garden radish [RAPHANUS *sativus*, in NAT. HIST. DIV.] furnish a colourless oil, heavier than water, and containing sulphur. It is probably the sulphide or the sulphocyanide of allyl.

Essential oil of ravensara. [EVODIA, in NAT. HIST. DIV.] Very similar to, and sometimes substituted for, oil of cloves.

Essential oil of rhodium. The root of Canary rosewood, *Genista canariensis*, yields by distillation this essential oil. It is of a light yellow colour, but by keeping becomes red; 100 lbs. of root yield about 1½ oz. of oil.

Essential oil of rosemary, prepared by distilling with water the tops of the plant. [ROSMARINUS, in NAT. HIST. DIV.] It is colourless, and has the characteristic taste and odour of the herb. Its sp. gr. is generally about 0·897, and boiling point 365° Fahr. It appears to be a mixture of hydrocarbon, oxygenised oil, and stearopten, in variable proportions.

Essential oil (or attar) of roses. [ATTAR OF ROSES.]

Essential oil of rue is capric or rutic aldehyde. [RUTIC ACID.]

Essential oil of saffron. Yellow, heavier than water. By exposure to air is converted into a solid crystalline substance. [CROCUS *sativus*, in NAT. HIST. DIV.]

Essential oil of sage. Obtained on distilling sage-leaves with water. It contains a hydrocarbon and an oxygenised portion. Nitric acid oxidises it to a crystalline body, having the odour and composition of laurel camphor. [SALVIA *officinalis*, in NAT. HIST. DIV.]

Essential oil of sandal-wood is procured by distilling the wood [PTEROCARPUS *santalinus*, in NAT. HIST. DIV.] with water. The yield is generally about two per cent. It is sometimes substituted for oil of rhodium and attar of roses.

Essential oil of sarsaparilla. In an experiment described by Pereira ('Materia Medica,' p. 1168), 140 lbs. of sarsaparilla root distilled with water yielded a few drops of an essential oil having the odour and acrid taste of the root, soluble in alcohol, and heavier than water.

Essential oil of sassafras. The wood [SASSAFRAS, in NAT. HIST. DIV.] yields on distillation with water a light yellow oil, of acrid taste and characteristic odour. Sp. gr. 1·094. On exposure to intense cold, large quantities of crystals are obtained from it. These have the formula $C_{20}H_{10}O_4$. Bromine acts violently on oil of sassafras, giving rise to a crystalline substitution product having the formula $C_{10}(H_2Br_3)O_4$.

Essential oil of savin. The fresh tops or berries [JUNIPERUS *sabina*, in NAT. HIST. DIV.] yield an essential oil of sp. gr. 0·915. It has the same composition and boiling point as oil of turpentine ($C_{20}H_{16}$).

Essential oil of scurvy-grass contains the sulphocyanide of allyl. [MUSTARD, OIL OF.] [COCHLEARIA *officinalis*, in NAT. HIST. DIV.]

Essential oil of senna. Exists in the leaves in rather small quantity. Extracted by distillation with water. It has a nauseous odour and taste. [CASSIA, in NAT. HIST. DIV.] [SENNA.]

Essential oil of spearmint. The herb [MENTHA *viridis*, in NAT. HIST. DIV.] furnishes not more than about two-tenths per cent. of an oil of sp. gr. 0·914. Its colour is pale yellow, deepening by age. It is nearly identical with oil of peppermint. [PEPPERMINT, *Essential oil of.*]

Essential oil of spike. Foreign oil of lavender. [LAVANDULA *spica*, in NAT. HIST. DIV.] It is chemically the same as the true oil of lavender (from *Lavandula vera*), but has a darker green colour and less grateful odour.

Essential oil of spikenard is another name for the so-called essential oil of geranium. See *Essential oil of grass.*

Essential oil of spiræa. The flowers of meadow-sweet (Reine des Prés), [SPIRÆA *ulmaria*, in NAT. HIST. DIV.] yield on distillation with water an essential oil containing a small quantity of a hydrocarbon isomeric with oil of turpentine, but consisting chiefly of an oxygenised body ($C_{14}H_6O_4$) that is identical with hydride of salicyl ($C_{14}H_5O_4,H$). [SALICYL, HYDRIDE OF]. Its specific gravity is 1·173, vapour-density 4·276, boiling-point 360° Fahr.

Essential oil of star-anise differs in odour, but is otherwise similar to that of the common anise. See *Essential oil of aniseed.* [ILLICIUM *anisatum*, in NAT. HIST. DIV.]

Essential oil of starch. According to M. Payen ('Pharmaceutical Journal,' vol. vii. O. S. p. 37) an essential oil pre-exists in the concentric layers of the grains of starch. About one ten-thousanth part of the starch is a yellowish liquid oil, having the characteristic smell of the starch in a high degree. Starch contains in addition a concrete oily matter less volatile than water. The fluid oil is lighter than water, and has a higher vapour-tension.

Essential oil of sweet bay. See *Essential oil of laurel-berries.*

Essential oil of sweet flag. The rhizome of the *Acorus calamus* [ACORUS, in NAT. HIST. DIV.] contains one per cent. of an essential oil principally composed of a hydrocarbon, but also containing an oxygenised portion. Neither have been thoroughly examined.

Essential oil of tansy is of a pale or golden yellow colour, sometimes green. It has a strong nauseous odour, and acrid bitter taste. Sp. gr. 0·931. [TANACETUM, in NAT. HIST. DIV.]

Essential oil of tarragon. The tarragon [ARTEMISIA *dracunculus*, in NAT. HIST. DIV.] furnishes an essential oil closely allied to *essential oil of aniseed.*

Essential oil of tea. Common tea [THEA, in NAT. HIST. DIV.] furnishes by distillation with water an oil lighter than water, and having in a high degree the characteristic smell of the tea. The odour of it excites giddiness to such an extent, that it may be said to be powerfully poisonous. The major part present in the fresh leaves is dissipated in the drying process they undergo.

Essential oil of templinum is the name given to an essential oil obtained in Hungary by distilling with water the young branches of the dwarf or mountain pine [PINUS *pumilio*, in NAT. HIST. DIV.].

Essential oil of thyme. By distilling with water common garden thyme. [THYMUS *vulgaris*, in NAT. HIST. DIV.]. It contains a hydrocarbon, and an oxygenised portion. [THYMENE; THYMOL.]

Essential oil of tobacco. By the dry distillation of tobacco, as for instance in the process of cigar or pipe smoking, an essential oil is produced that is one of the most violent of known poisons. By the distillation of tobacco leaves with water, a solid volatile oil is obtained having odour and taste characteristic of the drug. [NICOTIANA, in NAT. HIST. DIV].

Essential oil of tolu, obtained by distillation, is mainly a hydrocarbon *tolene*. It absorbs oxygen when exposed to the air, and becomes resinified. [MYROSPERMUM *toluiferum*, in NAT. HIST. DIV.] [BALSAMS.]

Essential oil of turpentine. [TURPENTINE.]

Essential oil of valerian. The root [VALERIANA *officinalis*, in NAT. HIST. DIV.] contains an essential oil of powerful odour. It consists of a hydrocarbon ($C_{20}H_{16}$) isomeric with oil of turpentine, and identical with bornéene [CAMPHOR], and of an oxygenised portion called *valerol* ($C_{12}H_{10}O_2$). [VALEROL.]

Essential oil of verbena. See *Essential oil of lemon-grass.*

Essential oil of vittie vayr or *vetiver* may be obtained from the fibrous roots sold by perfumers under the name of vittie vayr. On account of the essential oil contained in them, they are much used in India for scenting apartments, and for preserving clothing from the attacks of insects. They are the roots of a grass (*Andropogon muricatus*) closely allied to the English sweet vernal grass. The oil contains a hydrocarbon ($C_{20}H_{16}$) and an oxygenised portion. It is lighter than water.

Essential oil of wintergreen may be extracted from the flowers of the wintergreen [GAULTHERIA *procumbens*, in NAT. HIST. DIV.] by maceration in alcohol, or in ether. Nine-tenths of it are *gaultheric acid* ($C_{16}H_8O_6$) the salicylate of methyl ($C_{14}H_5O_5C_2H_3O$) or hydrate of methyl-salicyl ($HO,C_{14}H_4(C_2H_3)O_5$). The other tenth is a hydrocarbon, isomeric with oil of turpentine, called *gaultherilene.* The latter boils at 320° Fahr., vapour density 4·92.

Essential oil of winter's bark contains a pale yellow oil, lighter than water, and having a hot acrid taste. [WINTERACEÆ, *Drimys wintera*, in NAT. HIST. DIV.]

Essential oil of wormseed. See *Essential oil of chenopodium.*

Essential oil of wormwood. The herb [ARTEMISIA *absinthium*, in NAT. HIST. DIV.] yields an oil that, when pure, has the composition ($C_{20}H_{16}O_2$) sp. gr. 0·973, vapour-density 5·3. It is evidently isomeric with laurel camphor. [CAMPHOR.]

Essential oil of xanthoxylum. The Japanese pepper [XANTHOXYLUM *piperitum*, in NAT. HIST. DIV.] contains a hydrocarbon ($C_{20}H_{16}$) *xanthoxylene* to which the odour of the pepper is due, and a stearopten ($C_{40}H_8O_4$) called *xanthoxylin.*

Essential oil of zedoary. The tubers of the broad-leaved turmeric [CURCUMA *zedoaria*, in NAT. HIST. DIV.] yield a yellow, somewhat opaque oil having a camphorous odour and taste. It is composed of two oils, one lighter, the other heavier than water.

ESSOIGNS, Latin *Essonium*, French *Essoigne* (apparently from the Latin *Exonerare*), is the allegation of an excuse for non-appearance by a person summoned to answer an action at law, or to perform service at a court baron. There were various admitted causes of such excuse, such as illness, falling among thieves, floods, &c. And a party might essoign himself three times by sending a substitute to explain the reasons for his non-appearances. The first return day in every term was, properly speaking, the first day of the term; and on that day the courts formerly sat to take essoigns or excuses from such as did not appear to the summons or the writ; wherefore it was called the essoign day. But essoigns have become almost unknown in practice. They were confined to real and mixed actions. Of the former only three now remain, and these three are rarely resorted to, so that the learning relating to essoigns is almost lost.

ESTATE, in Law, signifies that title or interest which a man has in lands, tenements, hereditaments, or other effects. It is either real, comprising lands, tenements, and hereditaments held or enjoyed for an estate of freehold; or personal, comprising interests for terms of years in lands, tenements, and hereditaments, and property of every other description. Personal estate [CHATTELS] goes to the executors, and is primarily liable for payment of debts.

Real estate may be considered under three heads:—(1) the quantity of estate, *i. e.*, the amount of interest in the owner; (2) the time when that interest is to commence; and (3) the quality of estate, or the mode in which it is to be enjoyed.

1. All real estates not being of copyhold tenure [COPYHOLD], or what are called customary freeholds, are either of freehold or less than freehold. The former may be divided into two kinds; freeholds of inheritance, and freeholds not of inheritance. Freeholds of inheritance admit of a further subdivision, into inheritances absolute, called fee simple, and inheritances limited, called qualified or base fees, and fees conditional. A freehold of inheritance absolute of fee simple is the largest estate which the law allows to a subject; the owner may freely dispose of it to whom he pleases in his lifetime by deed or by will, and if he dies without making any disposition, it descends to such of his kindred as the law marks out as his heir.

A qualified or base fee has some qualification or limit annexed, which may determine the estate, as in the instance of a grant to A and his heirs *tenants of the manor of Dale.* Whenever A or his heirs cease to be tenants of that manor, their estate is entirely determined, though during its continuance the proprietor has the same rights and privileges as if he were absolute tenant in fee simple.

A conditional fee at common law was a fee restrained to some particular heirs exclusive of others, as to a man and the heirs male of his body, by which limitation his lineal heirs female and collaterals were excluded; and this is the origin of estates tail. It was held that if the donee, in the case supposed, had no heirs male of his body, or if, after a male child was born, no alienation were made, the land should revert to the donor on the failure of heirs male of the donee's body: in fact for all purposes of alienation it was a fee simple, on condition that the donee had male issue; for it is a rule of law, that when any condition is performed it is thenceforth entirely gone, and the thing to which it was annexed becomes absolutely and wholly unconditional. The nobility, however, being anxious to preserve their estates in their own families, procured the Stat. Westm. the Second, 13 Ed. I., c. 1, commonly called the Statute de Donis Conditionalibus, to be made, which enacted that the will of the donor should be observed, and that the land should go to the heirs specified, if there were any, or if none, should revert to the donor. Thus the donor acquired an estate in reversion, which could only be allowed, consistently with the nature of estates in reversion, by considering the conditional fee to be changed into a limited, or, as it is called in technical language, a particular estate. This kind of estate was called an estate *tail*, from the word *talliare*, to cut, being as it were a portion of the whole fee. Means were soon however discovered by the ingenuity of the lawyers to enable the donee and his heirs of the specified description to cut off the entail, as it was called. [CONVEYANCE; FINE; RECOVERY.]

A freehold, not of inheritance, is an estate which the owner has for his own life only, or the life of some other person, or until the happening of some uncertain event. The following are instances:—A gift to A until B returns from Rome; but if the gift had been to A and his heirs until B returns from Rome, the estate would have been a qualified or base fee; and if B had died without returning from Rome, would have become a fee simple absolute. Some freeholds not of inheritance, arise from operation of law, as tenant in tail after possibility of issue extinct, which is where an estate is limited to A and the heirs of his body to be begotten on the body of B his wife, which is called an estate tail special (as distinguished from an estate tail general, *i. e.* to A and the heirs of his body, without specifying the woman from whom they must spring). If B dies without children, A is no longer tenant in tail, but tenant in tail after possibility of issue extinct, and is regarded by the law, as to the duration of his estate, as simple tenant for life. As to tenant by courtesy and tenant in dower, see COURTESY and DOWER.

Of estates less than freehold there are three kinds—estates for years, at will, and by sufferance. An estate for years (which includes an estate from year to year) is personal property, and, like other chattels [CHATTELS], upon the death of the owner, without having disposed of it in his lifetime, devolves upon his executors or administrators. An estate at will arises where a man lets lands to another expressly at the will of both parties or without limiting any certain estate; either party may put an end to the tenancy, though, for the sake of general convenience, the courts strive to construe them as tenancies from year to year, for the purpose of rendering a six months' notice necessary to their determination. An estate by sufferance arises where a tenant, who has entered by lawful title, continues in possession after his intrest has determined: this estate may be put an end to at any time by the lawful owner, though, after acceptance of rent, the law would consider it as a tenancy from year to year, as in the case of a tenancy at will.

Neither of these two last estates confers any power of alienation. All these estates, real and personal, freehold or less than freehold, freeholds of inheritance or not of inheritance, may become subject to another qualification, and be called estates upon condition, being such whose existence depends upon the happening or not happening of some uncertain event whereby the estate may be either originally created or enlarged or finally defeated. [CONDITION; MORTGAGE.]

2. Estates are either in possession or in expectancy.

The former kind of estate requires no explanation here. The latter, involving some of the nicest and most abstruse learning in English law, are divided into estates in remainder and reversion, and by executory devise or bequest; and again, remainders are divided into estates in remainder vested or contingent. [REMAINDER; REVERSION.] An executory devise or bequest is such a limitation of a future estate or interest in lands or chattels as the law admits in the case of a will, though contrary to the rules of limitation in conveyances at common law. It is only an indulgence allowed to a man's last will and testament, where otherwise the words of the will would be void; for wherever a future interest is so limited by a will as to fall within the rules laid down for the limitation of contingent remainders, such an interest is not an executory devise, but a contingent remainder. [WILL.]

3. Estates may be enjoyed in four ways; in severalty, in joint tenancy, in coparcenary, and in common.

An estate in severalty is when one tenant holds it in his own right without any other person being joined with him.

An estate in joint tenancy is when an estate is granted to two or more persons at the same time, in which case the law construes them to be joint tenants, unless the words of the grant expressly exclude such construction; they have unity of interest, of title, of time of vesting, and of possession, and upon the decease of one, his whole interest, unless disposed of by him in his lifetime, remains to the survivor or survivors.

An estate in coparcenary is when an estate of inheritance descends from the ancestor to two or more persons, who are called parceners, and amongst parceners there is no survivorship.

An estate in common is when two or more persons hold property, by distinct titles and for different interests, but by unity of possession.

All these three last-mentioned modes of joint and undivided possession may be put an end to by the parties interested, either by prescribed modes of conveyance or by partition. [PARTITION.]

Estates are also legal or equitable. It is a legal estate when the owner is in the actual seisin or possession, and also entitled to the beneficial interest himself or in trust for some other person. An equitable estate is when some other person, and not the person who is the actual and legal owner, is entitled to the beneficial interest of the property of which that other is in possession. The power of the beneficial owner over his equitable estate is as complete as if he were possessed of the legal estate. [TRUST; EQUITY.]

ESTHER, The Book of, a canonical and historical book of the Old Testament, placed after that of Nehemiah, but coming chronologically between the 6th and 7th chapters of Ezra. It is thus denominated from the Persian name of the Jewish woman, Hadassah, whose history it relates. She was an orphan niece and adopted daughter of Mordecai, from a Benjamite family of the Babylonian captives of Nebuchadnezzar (ii. 5-7). The scene of the narration is in the city Shusan, or Susa, now Sus (not Shuster, as stated by Dr. Adam Clarke—see 'Trans. Geog. Soc.,' vol. iii.), which, throughout the book, is in English mistranslated Shushan the *palace*, though, in the Septuagint version, it is rightly *ἐν Σούσοις τῇ πόλει*, that is, "in Susa the city." Augustine, Epiphanius, and Isidore, supposed the author to have been Ezra. Eusebius assigns a later date. Some writers have attributed it to the high-priest Joachim; others believe it to have been composed by the Jewish synagogue, to whom Esther and Mordecai wrote (ix. 20-29); but by the greater number Mordecai himself is thought to be the author, and Elias Levita, in his 'Mass. Hamum,' asserts this to be a fact unquestionable. St. Hieronymus and several other fathers regarded this book as wholly uncanonical, because the name of God or religion is not once mentioned or alluded to, and they have been followed by some modern writers, as Cajetan and De Lyra; but the Council of Trent pronounced it to be wholly canonical; and while the Protestant churches admit into the canon only what is found in the Hebrew copies, that is, as far as to the end of the third verse of chap. x., the Greek and Roman churches use as canonical the Greek version and Latin Vulgate, which contain each ten more verses of chap. x. and six additional chapters. By the Jews the book has been always considered as one of the most precious of their sacred scriptures, and as a perfectly authentic history of real events which took place about B.C. 519. They call it מגילה, Megilah, that is, *The* Volume, and hold it in the highest estimation; believing that whatever destruction may happen to the other scriptures, Esther and the Pentateuch will always be preserved by a particular Providence. Copies exist in the Hebrew, Syriac, Chaldaic, Greek, and Latin, each of which widely differs from the others, and all, especially the Greek and Chaldaic, are greatly different from the Hebrew. The Chaldaic text contains five times more than the Hebrew, and a notice of the various readings would fill a large volume. (See the London Polyglot Bible.) Commentators differ much in determining to which of the Persian and Median kings belongs the name of Ahasuerus, whose kingdom extended from India to Ethiopia over 127 provinces (i. 1). Some suppose him to be Darius Hystaspes, Scaliger and Jahn say Xerxes. By Capellus he is identified with Ochus, and by Archbishop Usher with Darius the son of Hystaspes. Dean Prideaux and Dr. Adam Clarke with greater probability take him to be Artaxerxes, who received the cognomen of Longimanus, or Longhanded. To the objections that have been made that the book is a fiction, Eichhorn has satisfactorily replied, proving that it rests upon an historical basis; and as to its not being included in some lists of the canonical books of the Hebrews, that may have arisen from its having been joined to some other book, as that of Ruth was to Judges, Nehemiah to Ezra, and Lamentations to Jeremiah. The author of the second book of Maccabees recognises its authority by fixing the day for the deliverance of the Jews from the Syrian on the day before Mardocheus' day; and Josephus says that the feast of Esther was celebrated by the Jews throughout the habitable world.

This signal revenge of Haman's intended destruction of the Jews in Persia has ever since been commemorated (ix. 21-28) on the 14th and 15th days of the month Adar, in the Jewish 'Feast of Purim,' that is, in Persian, *the lots*; with reference to those which, on this occasion, were cast before Haman (ch. iii. 7; ix. 26). It is here worthy of remark, that the word which in the authorised version is repeatedly translated *gallows*, should properly be *cross* or tree. Hence it was that in the first ages of Christianity, the Jews, when celebrating this feast of Purim, were accused of deriding the Christian crucifixion, in abusing and setting fire to an effigy of Haman affixed to a lofty wooden *cross*; a custom which, on this account, was abolished in the Roman Empire by the decrees of Justinian and Theodosius. That the names of God or Lord are not mentioned in the book, is certainly a singular fact, but the whole tendency of the book is pious; it shows the continued action of the Divine Providence in preserving a race from whom the Messiah was to spring; and, though not mentioned, the presence and the intervention of God is throughout made to be felt.

ESTOPPEL, an impediment or bar to a right of action, arising from a man's own act, or the act of some person through whom he claims. There are three kinds of estoppel. 1. *By matter of record*, as letters patent, pleading, &c. Thus in an action against a patentee by his assignee, the patentee is estopped from pleading that the patent is invalid.

2. *By matter of writing*, as by deed, &c., parties and privies are estopped from alleging any thing contrary to the deed.

3. *By matter in pais* (in the country), that is, transactions between the parties not evidenced by record or writing, as livery, entry, acceptance of rent, &c. Thus after acceptance of rent a landlord cannot treat his lessee as a trespasser.

ESTOVERS. Spelman, in his Law Glossary, says that this word is derived from the French *étoffe*, and that from *étoffer*, which is to supply with necessaries, and is of the same signification as the Saxon word *bote*. In legal phraseology it is the liberty which the owner of an estate for life as well as a tenant for years (in the absence of any stipulation to the contrary) possesses of taking a reasonable and necessary supply of wood from the estate for the use or furniture of his house or farm, and this, according to the use to which it was applied, was either called house bote, plough bote, cart bote, or hedge bote. *House bote* is a sufficient allowance of wood to build or repair the house, or to burn in it, which latter is also sometimes called *fire-bote*; *plough-bote* or *cart bote* is the wood employed in the making or repairing all instruments of husbandry, as carts and ploughs, harrows, rakes, &c.; *hedge bote* or *hay bote* for repairing hedges, fences, pales, stiles, and gates, and to secure inclosures.

If a tenant takes more than is needful for these purposes he may be punished for waste, as if he cuts down wood to burn when he has sufficient dead wood upon the estate; and a tenant, although he may cut down and take sufficient wood to repair pales and fences as he found them, cannot do so to make new ones.

A rector may also cut down wood for the repair of his parsonage-house or the chancel, and even for any old pews which belong to the rectory: and, like other tenants for life, he is entitled to estovers for repairing the barns and out-houses belonging to the parsonage.

Bracton uses the word estovers in a different sense, viz., as the sustenance, which a man committed for a felony is to have out of his lands and goods for himself and family during his imprisonment; it also occurs in the statute 6 Ed. I. c. 3, as an allowance of meat or cloth; but the more common and usual signification by which it is known to lawyers has been already stated. (Woodfall, *Landlord and Tenant*; Comyn.)

ESTRA'NGELO, or ESTRANGHELO, is the name of the most ancient of the three kinds of characters used in writing the Aramæan or Syriac language. The alphabet so called, of which there is a copy in the Prolegomena to Walton's 'Polyglot,' p. 11, is distinguished by the stiffness and angular forms of the letters from that found in all printed Syriac books, which is denominated facitto (that is, simple), or sertto (linear). A character nearly resembling the Estranghelo is stated to be still commonly used in writing by the Nestorians and some of the Melchitæ. It is believed to have been originally common to all the nations or tribes speaking any Chaldaic dialect. The Syriac grammarians also enumerate a third alphabet, which they designate the eefifo (meaning the duplicated), or the mesttariono (the split); but this is merely an alphabet of what we should call open letters, used for ornamental purposes.

See 'Grammatica Syriaca, sive Chaldaica, Georgii Michaelis Amiræ Edeniensis è Libano,' 4to, Rom. 1596, cap. i., where copies of all the three alphabets are given.

ESTRAY, any valuable tame animal found wandering at large within any manor or lordship, and whose owner is unknown. Having been impounded, and proclaimed in the church and the two nearest market-towns on a market-day, it becomes, if not claimed in a year and a day, the absolute property of the king, as lord paramount of the soil, though generally the lord of the manor or liberty is the special grantee of the crown. Animals upon which the law sets no value, as a dog or a cat, or such as are of a wild nature, as a fox or a wolf, cannot be taken as estrays. Swans may be taken as estrays, but no other fowl. The king or the lord does not acquire the absolute property in the estray until the full expiration of the year and a day, which runs from the first proclamation, and not from the seizure; therefore if it escape before the time to another manor he cannot reclaim it.

The king or the lord is bound to take care of the estray, and find it in provision; he must not use it, but is liable to an action for so doing, though he may milk a cow or the like, for that tends to the preservation of the animal, and is necessary. The owner on the other hand, if he claims within the time allowed, must pay the charges of finding, keeping, and proclaiming the estray.

It may be observed, that if any person not being entitled to estrays, finds and takes care of another's property, the owner may recover it or its value without being obliged to pay for the expenses incurred in keeping it.

ESTREAT, from the Latin word *extractum*, is a true copy or note on the rolls of a court of some original writing or record, especially of fines and amerciaments which are to be levied by a bailiff or other officer. In all cases of felony or misdemeanor where persons bound by recognisance either to appear themselves, or for the attendance of any witness on trials of felonies or misdemeanors, neglect to do so, the recognisance becomes forfeited; an officer of the court, whose duty it is at the end of the assize or session, prepares a list of the defaulters, and when the same has been approved by the judge presiding, the fine or forfeiture mentioned in the recognisance is said to be estreated or certified into the Exchequer, and process is awarded for its recovery.

These fines, when levied, are paid into the Treasury, or the lords of the Treasury may, if they think fit previously to the issuing of the process, stay the execution and remit the fine.

The barons of the Exchequer were also empowered by a standing writ of privy seal to discharge, mitigate, or compound forfeitures estreated into the Exchequer from other courts; and by the 4th Geo. III. c. 10, they are also authorised, upon affidavit and petition, to discharge estreated recognisances and forfeitures, except those incurred before justices of the peace.

ETCHING. [ENGRAVING.]

ETESIAN WINDS. [WINDS.]

ETHAL, a substance separated from spermaceti by Chevreul. It is a solid, fusible at nearly the same point as spermaceti, and on cooling crystallises in plates. It is insoluble in water; but in alcohol at 150° Fahr. it is much more soluble than spermaceti. Ethal is susceptible of union with various bases, with which it forms salts or soaps. [CETYL, *Hydrate of cetyl.*]

ETHALIC ACID. [PALMITIC ACID.]

ETHALONE. [PALMITONE.]

ETHANIM, אֵתָנִים, like Zif and Bul, is an ancient Hebrew name of the month called now Tisri, the first month of the civil year. These months are nowhere named in the Bible, except in two chapters of the first book of Kings: Ethanim is in ch. viii. v. 2, and it is there called the seventh month of the year, which place it held in the calendar until the middle of the 4th century A.D., when the commencement of the year was altered from spring to autumn. According to some Jewish authorities this change was made with a view to restoring an original form of the calendar said to have been in use from the creation of the world, which was believed to have occurred at the autumnal equinox; and this appears to be the view of the Chaldee paraphrast of the verse above mentioned, who renders it "In the month which they [anciently] called the first month, and which is now the seventh." Buxtorf, who quotes this passage from the Targum, says that the old usage ceased after the Exodus.

The word Ethanim appears to be derived from אֵיתָן strong, rough. It is also said to signify 'running streams.' There is no evidence of its having been used since the days of Nehemiah, though the name Tisri, now in use, which must signify 'a beginning,' from the root שָׁרָה, could hardly have been adopted before the alteration of the calendar, many centuries after Nehemiah; and even if we stretch our confidence in the tradition so far as to admit of a more ancient calendar in which the year began in autumn, a word which implies 'beginning' could hardly have continued in use for the appellation of a month occurring in the middle of the year.

ETHER, *Medical Properties of*. It is intended here only to notice the medical uses of ethers long known, with a few of those more recently introduced. The first to be treated of, after giving a brief general view of their modes of action on the human system, is sulphuric ether, which is always understood to be the one indicated when the term ether is employed absolutely. The German chemists and therapeutists designate them *naphthæ*, a term liable to cause them to be confounded with *bitumens*. Ethers present the most perfect examples of volatile stimulants, being unequalled for rapidity of action, when immediate aid must be imparted to the muscular system, especially the involuntary muscles, by augmenting the nervous power, and by quickening its development. Whether they effect this by a direct impression on the nerves, or by previous absorption into the circulation, it is very difficult to determine, since most of them are absorbed so rapidly as almost instantly to mix with the circulating mass. They bear the greatest resemblance to alcoholic stimulants; but are distinguished by more instantaneous effects. These however are more transient, and a more frequent repetition of the dose is therefore required. Fatal results are less likely to follow from large doses of ether than of alcohol, a fact which can only be accounted for by the excess being more speedily thrown out of the system, especially by pulmonary and in some degree by cutaneous exhalations; for the more highly carbonised constitution of ether would lead us to expect a contrary result. This furnishes the proper guide for the treatment of cases of poisoning by them, namely, placing the patient where he may respire as pure air as possible, and in the light, carrying on artificial respiration if needful, occasionally dashing cold water on the face and temples, and cautiously using venesection or cupping. Transmitting a galvanic current of a moderate force along the eighth pair of nerves is often beneficial. Perseverance in the use of these means for hours is frequently successful. Sulphuric ether is the most powerful of etherial preparations, and therefore of diffusable stimulants. It is distinguished from the others likewise by having less secondary effects upon the system. Hence it is more employed for its primary effects than for both primary and secondary effects. It is of a peculiar, strong, penetrating, rather agreeable odour; the taste is at first cooling, afterwards hot, leaving a feeling of dryness in the mouth and throat. Its volatility is very great, and though it does not excite redness of the mucous membrane of the stomach in a moderate dose, yet being quickly changed into vapour by the heat of that organ, it causes contraction of its muscular coat, and expulsion of gas, thus acting as a carminative, or it produces most painful distension if that viscus be not powerful enough to resist its local action, and is followed by slight cerebral excitement, and even a feeling similar to intoxication may be experienced, which however soon passes off, without leaving any marked depression; though a disposition to sleep, and sometimes tendency to perspiration, are the ultimate consequences. The lungs are the common channel by which it is eliminated; this ether having less influence on the kidneys or skin than the other sorts. If spasm, irregular action, or debility of the organs of circulation, respiration, or digestion, existed previous to its administration, these generally disappear speedily, or are alleviated by its use. Hence it ranks as an antispasmodic of the highest kind. It is therefore resorted to in all cases of imminent danger, from difficulty of breathing, colic, flatulence, and deep depression, such as occurs in cholera Asiatica, or the later stages of fever. In relieving paroxysms of asthma it is unrivalled, and may be inhaled along with the vapour of warm water, or by being dropped on a portion of sugar held between the teeth. Like all stimulants, habit diminishes its influence on the system, so that the dose requires to be greatly increased. So much as two ounces have been taken by an adult in twenty-four hours. This is hazardous, and the necessity for it may be diminished by alternating sulphuric ether with some of the other ethers, which, though little known or used in this country, are found very effectual by the German, French, and American practitioners. An increase of our etherial preparations would be a valuable accession to our curative agents. Economy and physiology alike recommend the proceeding. The great solvent power of sulphuric ether renders it an eligible menstruum for the administration of a variety of articles; by these its own powers are heightened. It has also been attempted to take advantage of its power in this respect, by employing it in cases of biliary calculi, not merely to alleviate the agonising pain, but from a belief that it would dissolve the calculus, and so lessen its bulk. Oil of turpentine is a good addition. It has also been recommended against tape-worm, from a notion that the volatised ether would greatly annoy the worm, and allow it to be easily removed by a dose of castor oil or other purgative. This is not free from inconvenience and even danger to the feeble persons who are infested with the tape-worm. The antispasmodic powers of ether are much increased by adding tincture of opium, or a solution of the hydrochlorate of morphia. This combination furnishes the most effectual means of warding off a paroxysm of hysteria or epilepsy, if administered promptly. This is an object of great moment, as every fit, if allowed to take place, predisposes to a recurrence of them. Externally, ether is applied to the temples to relieve nervous headaches; and also over hernial tumours, in order that by the cold consequent on its evaporation the hernia may contract and be reduced: a portion of thin oiled silk should lie interposed between the ether and the skin.

Sulphuric ether is rarely found in shops perfectly pure. The casual or intentional adulterations interfere more with its chemical properties as a solvent of various substances than with its medicinal powers. Time however resolves it, particularly if kept in the light, into acetic acid and alcohol. It ought therefore to be recently prepared, and preserved in an obscure place. The Spirit of sulphuric ether is only a weaker form, with some etherial oil, of the pure ether.

Nitric or hyponitrous ether is never employed pure in medicine, but only as the spirit of nitric ether. This has considerable resemblance to the sulphuric ether, but is more miscible with water. It likewise has more marked secondary effects, especially on the kidneys and skin. Hence it is much employed as a diuretic. Its impression on the organ of taste is aromatic, sweet, and cooling, and it is known familiarly as the Sweet Spirit of Nitre. Its restorative action is neither so quick nor so certain as that of sulphuric ether; but where dropsical effusions co-exist with disease of the heart, it merits the preference. It is charged with uncertainty as a diuretic, less perhaps from its own nature, than from want of accurate discrimination of the varieties of condition both of the system at large and of the kidneys, when diuretics are indicated, and from the very common error of mingling in the same formula medicines of very opposite modes of action, though each singly may be a diuretic. [Diuretics.] The vapour of this, as well as of sulphuric ether, when copious, has proved fatal to those exposed to it. All bottles containing them should be well stopped or corked. Sweet spirit of nitre is a useful addition to copaiba, both as aiding to convert it into the form of mixture, and as a diuretic for diluting the acrimony of the urine, where copaiba is given in diseases of the bladder and urethra. (Christison.) Nitric ether is often fraudulently added to malt spirits to give them the flavour of French brandy. (Paris.)

Chloric ether is also markedly diuretic. It is a most valuable analeptic in the sinking stages of fevers, in asthma, and asthenic diseases of various kinds.

Acetic ether is a very agreeable stimulant, possessing a grateful odour, resembling Rhine wine, and a cooling, aromatic, somewhat bitterish taste. Its action is similar to that of the other ethers, and though not so potent, it is more agreeable to take. Its long-continued use however oppresses the digestive organs. Nevertheless it deserves to be employed in adynamic fevers, its action on the skin rendering it very advantageous. In tendency to fainting it is very serviceable; also in asphyxia. In some local affections it is of great utility applied in the form of vapour, such as some forms of deafness. (See Pilcher 'On the Ear.')

Phosphoric ether is a valuable restorative in the paralytic stage of fever.

For the employment of sulphuric ether as an anæsthetic agent, see Chloroform, and the work of Dr. J. C. Warren on 'Etherization.' Boston, U.S., 1848.

Collodion, which is a solution of gun-cotton in ether, is of considerable use in medicine. As a means of excluding the air from cuts, cracks, and sores, it is often better than ointments. It lessens the tendency to form pits and depressions of the skin in small pox, and is very effectual in stopping profuse bleeding from leech-bites.

ETHER, AMYLIC. Synonymous with *oxide of amyl.* [Amyl.]

ETHER, BUTYRIC. [Butyle.]

ETHER, CAMPHORIC. [Camphoric Acid.]

ETHEREAL SALTS. These organic bodies, called also *ethers* and *Compound Ethers*, are, like the true ethers, formed upon the model or type of water; they differ however from the ethers, inasmuch as one of the radicals replacing hydrogen is a negative radical. Thus, formic ether consists of water, in which one of the equivalents of hydrogen is replaced by the positive radical ethyl, and the remaining atom of hydrogen by the negative oxygenous radical formyl.

Formic ether . . . . $\left.\begin{array}{l}C_4H_5\\C_2HO_3\end{array}\right\}O_2$

The constitution of these compounds is analogous to that of the salts of the oxygen acids amongst inorganic bodies.

The ethereal salts are produced by a variety of processes; for instance by the reaction of the alcohols upon the hydrated acids, the anhydrous acids, or the chlorides of the acid radicals. The hydrated organic acids generally require the intervention of sulphuric or hydrochloric acid to etherify them. The anhydrous acids are more easily etherified than the hydrated. Sometimes hydrated acid may be etherified by heating it with the simple ether in a sealed tube to about 650° Fahr. This is the case with the butyric, benzoic, and palmytic acids.

The ethereal salts are generally very mobile colourless liquids, possessing peculiar and often very agreeable odours, the fragrance of many fruits and flowers being due to the presence of small quantities of these bodies. They are neutral, volatile, and generally very sparingly soluble in water. Ammonia converts many of these ethereal salts into amides. [For the nature of the reaction see Amides.]

The above remarks refer exclusively to *monatomic* ethereal salts, that is, ethers constructed upon the model of the double molecule of water; there are, however, other classes of ethereal salts derived from bibasic and tribasic acids, and which are termed respectively *biatomic* and *triatomic* ethereal salts. The biatomic ethereal salts correspond to the quadruple molecule of water, thus:

$$\underbrace{\left.\begin{array}{l}H\\H\\H\\H\end{array}\right\}O_4}_{\text{Water.}}\qquad\qquad\underbrace{\left.\begin{array}{l}C_4H_5\\C_4H_5\\C_2O_3\\C_2O_3\end{array}\right\}O_4}_{\text{Oxalic ether.}}$$

Whilst the triatomic ethereal salts are constructed upon the model of the sextuple molecule of water, thus:

$$\underbrace{\left.\begin{array}{l}H\\H\\H\\H\\H\\H\end{array}\right\}O_6}_{\text{Water.}}\qquad\qquad\underbrace{\left.\begin{array}{c}C_2H_3\\C_2H_3\\C_2H_3\\Cy\\Cy\\Cy\end{array}\right\}O_6}_{\text{Cyanate of methyl.}}$$

The biatomic and triatomic ethereal salts are produced by processes analogous to those employed for the preparation of the monatomic ethereal salts, with which they also possess great similarity of properties. A detailed description of these ethers is, when necessary, given under the name of the positive radical (Ethyl, for instance) which they contain.

ETHERENE. [Olefiant Gas.]

ETHERINE. Etherol. *Light oil of wine* ($C_{32}H_{32}$?). A peculiar oily hydrocarbon, formed during the preparation of ether. It boils at 526° Fahr.

ETHEROL. [Etherine.]

ETHERONE. Identical with Amylene.

ETHERS. This name has been applied in chemistry to three distinct classes of bodies, namely, 1st, to a series of compounds constituted like ether $\left(\text{vinic ether }\left.\begin{array}{l}C_4H_5\\C_4H_5\end{array}\right\}O_2\right)$; 2nd, to a class of bodies formed by the union of organic radicals like ethyl with the halogens, chlorine, iodine, &c., as

Iodide of ethyl . . . . C_4H_5I
Chloride of methyl . . . . C_2H_3Cl;

and 3rd, to a family of organic compounds, of which acetic ether $\left(\left.\begin{array}{l}C_4H_5\\C_4H_3O_2\end{array}\right\}O_2\right)$ may be taken as a type. To the first class of substances exclusively, we propose to apply the designation *Ethers*, the second may be conveniently termed *Haloid Ethers*, and the third *Ethereal Salts*.

Ethers. Several bodies belonging to this class have been long known; but although few organic compounds have been submitted to more elaborate investigation, yet it was not until the publication of the recent remarkable researches of Professor Williamson that the true nature and constitution of this important class of organic bodies became clearly established. According to this chemist, the ethers are constructed upon the type of the double atom of water, the same in fact upon which the alcohols are considered to be formed; but whilst in the alcohols only one of the equivalents of hydrogen in the double atom of water is replaced by a compound radical, in the ethers both equivalents of hydrogen are thus replaced.

These relations of alcohols and ethers to water will be best seen from the following examples:—

Water . . . . . . $\left.\begin{array}{c}H\\H\end{array}\right\}O_2$
Vinic alcohol . . . . . $\left.\begin{array}{c}C_4H_5\\H\end{array}\right\}O_2$
Vinic ether . . . . . $\left.\begin{array}{c}C_4H_5\\C_4H_5\end{array}\right\}O_2$

Sometimes the two equivalents of hydrogen in water are replaced by two different radicals, constituting what is termed a *mixed ether*, thus :—

$$\text{Methylovinic ether} \quad . \quad . \quad . \quad . \quad \left.\begin{matrix}C_2H_3\\C_4H_5\end{matrix}\right\}O_2$$

The ethers are produced either by distilling the corresponding alcohols with concentrated sulphuric acid, which abstracts water from them,

$$\underbrace{2\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Vinic alcohol.}} = \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}O_2}_{\text{Vinic ether.}} + \left.\begin{matrix}H\\H\end{matrix}\right\}O_2$$

or by treating the potassiated alcohol with a haloid ether, thus :—

$$\underbrace{\left.\begin{matrix}C_4H_5\\K\end{matrix}\right\}O_2}_{\text{Ethylate of potash.}} + \underbrace{\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} = \underbrace{\left.\begin{matrix}K\\I\end{matrix}\right\}}_{\text{Iodide of potassium.}} + \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}O_2}_{\text{Vinic ether.}}$$

The mixed ethers are most conveniently produced by the last re-action, thus :—

$$\left.\begin{matrix}C_4H_5\\K\end{matrix}\right\}O_2 + \underbrace{\left.\begin{matrix}C_2H_3\\I\end{matrix}\right\}}_{\text{Iodide of methyl.}} = \left.\begin{matrix}K\\I\end{matrix}\right\} + \underbrace{\left.\begin{matrix}C_2H_3\\C_4H_5\end{matrix}\right\}O_2}_{\text{Methylovinic ether.}}$$

The ethers are generally liquid at ordinary temperatures, but methylic ether is gaseous, and some of the higher terms of the family (as cetylic ether) are solid. They are neutral in their action upon test-papers, and are generally volatile without decomposition. In contact with strong acids they behave like the corresponding alcohols, although their affinities are of a less energetic character. A description of each ether will be found under the head of its constituent radical; thus, methylic ether under METHYL, and vinic ether under ETHYL.

Haloid Ethers. The haloid ethers constitute, in organic chemistry, a family of bodies occupying a position analogous to that of the hydracids, as hydrochloric acid, in inorganic compounds. In fact a hydracid is transformed into a haloid ether by replacing its hydrogen by an equivalent of a positive organic radical. Thus :—

$$\underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Alcohol.}} + \underbrace{\left.\begin{matrix}H\\Cl\end{matrix}\right\}}_{\text{Hydrochloric acid.}} = \left.\begin{matrix}H\\H\end{matrix}\right\}O_2 + \underbrace{\left.\begin{matrix}C_4H_5\\Cl\end{matrix}\right\}}_{\text{Chloride of ethyl.}}$$

The haloid ethers closely resemble the ethers in their appearance; they are volatile odoriferous bodies, mostly liquid, although a few are gaseous, and others solid. In contact with alcoholic solution of potash they are decomposed, the alcohol from which the haloid ether was derived being regenerated.

$$\underbrace{\left.\begin{matrix}C_4H_5\\Cl\end{matrix}\right\}}_{\text{Chloride of ethyl.}} + \underbrace{\left.\begin{matrix}K\\H\end{matrix}\right\}O_2}_{\text{Hydrate of potash.}} = \underbrace{\left.\begin{matrix}K\\Cl\end{matrix}\right\}}_{\text{Chloride of potassium.}} + \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Alcohol.}}$$

The haloid ethers containing iodine are decomposed by zinc at elevated temperatures, with the separation of the radical. [ETHYL.] A description of the different haloid ethers will be found under the respective compound radicals.

ETHICS is the science which relates to our mental affections, not simply as a phenomena, but as they are virtuous or vicious, right or wrong. The term is derived from the Greek ἠθική, which is equivalent with the Latin *mos, mores*, whence the adjective *moralis*, and the English word *morals*. Aristotle, in the second book of his 'Ethics,' addressed to his son Nicomachus, says that moral science received the name of ethics from the word *éthos* (ἔθος), 'habit, use, or custom,' (ἠθικὴν, ἀπὸ τοῦ ἔθους, or ἀπὸ τῶν ἠθῶν), since it is from habitual experience, and routine of customary conduct that moral dispositions and principles are gradually formed and changed. Cicero, in his work on Moral Ends ('De Finibus,' 1 and 5), briefly defines ethics, or morality, as the 'ars vivendi,' or 'doctrina bene vivendi,' that is, the art of living wisely. The scholastic treatises on ethics divide the practical part of the science into three departments, *éthike* (ἠθική), which shows by appropriate precepts what is the duty of a good man; *aconómike* (οἰκονομική), which shows what is the duty of a good father of a family; and *politike* (πολιτική), which exhibits the duty of a good citizen, and of a good magistrate. [MORALS.]

ETHIONIC ACID (C_4H_4, $2HO$, $4SO_3$). This acid is prepared by passing the vapour of anhydrous sulphuric acid slowly into absolute alcohol kept cold; by their mutual action an oleaginous fluid is formed, without the evolution of any gaseous matter. This fluid is to be mixed with water and saturated with baryta, by which a portion of sulphate is separated, and ethionate of baryta is obtained by evaporation in vacuo.

Ethionic acid may also be prepared by the action of anhydrous sulphuric acid upon olefiant gas.

ETHIOPS' MINERAL. [MERCURY, *sulphide of.*]

ETHYL $\left(\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}\right)$. This Organic Radical is one of the most important of the class of chemical compounds to which it belongs. It is not only capable of being obtained in a separate or free state, but it also forms a more numerous and better studied class of organic compounds than any other organic radical. In all its compounds it stands in the same relation to the element or elements with which it is united, as hydrogen occupies when analogously united with the same elements. Thus we have

$$\underbrace{\left.\begin{matrix}H\\H\end{matrix}\right\}O_2}_{\text{Oxide of hydrogen, or water.}} \quad \text{and} \quad \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}O_2}_{\text{Oxide of ethyl, or ether.}}$$

$$\underbrace{\left.\begin{matrix}C_4H_3O_2\\H\end{matrix}\right\}}_{\text{Acetic acid.}} \quad \text{and} \quad \underbrace{\left.\begin{matrix}C_4H_3O_2\\C_4H_5\end{matrix}\right\}O_2}_{\text{Acetic ether.}}$$

$$\underbrace{\left.\begin{matrix}H\\I\end{matrix}\right\}}_{\text{Hydriodic acid.}} \quad \text{and} \quad \underbrace{\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}}$$

$$\underbrace{N\left\{\begin{matrix}H\\H\\H\end{matrix}\right.}_{\text{Ammonia.}} \quad \text{and} \quad \underbrace{N\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.}_{\text{Triethylamine.}}$$

These examples, which might be greatly multiplied, show that ethyl possesses the closest chemical relationship to hydrogen, and as hydrogen in its elementary or free condition is now usually represented by chemists as a double atom $\left(\left.\begin{matrix}H\\H\end{matrix}\right\}\right)$, so the formula of ethyl is now usually written double $\left(\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}\right)$

Ethyl may be readily prepared in a state of purity by decomposing iodide of ethyl by granulated zinc, in a sealed glass tube, at a temperature of about 300° Fahr. The following decomposition takes place :—

$$\underbrace{2\left.\begin{matrix}C_4H_5\\I\end{matrix}\right\}}_{\text{Iodide of ethyl.}} + Zn_2 = \underbrace{2\left\{\begin{matrix}Zn\\I\end{matrix}\right.}_{\text{Iodide of zinc.}} + \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}}_{\text{Ethyl.}}$$

Simultaneously with this reaction there occurs another, by which *zincethyl* is produced (see *zincethyl*, col. 982). A portion of the ethyl is also decomposed into hydride of ethyl and olefiant gas.

$$\underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}}_{\text{Ethyl.}} = \underbrace{C_4H_4}_{\text{Olefiant gas.}} + \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}}_{\text{Hydride of ethyl.}}$$

On breaking off the extremity of the sealed glass tube beneath the edge of an inverted receiver filled with water and standing on the shelf of the pneumatic trough, the gaseous products of the decomposition, namely, ethyl, olefiant gas, and hydride of ethyl, rush out with great violence; but, owing to a portion of the ethyl being liquified in the tube by the great pressure, that body requires more time for its complete gasification than is necessary for the complete expulsion of the hydride of ethyl and olefiant gas: consequently, if the last portion of gas be collected apart, it is found to consist of pure ethyl.

Ethyl is a colourless gas, possessing a very slight ethereal odour, burning with a brilliant white flame, and having a specific gravity of 2·0039. It is incondensable at a temperature of 0° Fahr., but exposed to a pressure of 2¼ atmospheres at 37° Fahr. it condenses to a colourless, transparent, and mobile liquid, which instantly resumes the gaseous condition on the pressure being removed. Its boiling point is consequently about —9·5° Fahr. Alcohol absorbs about 18 times its volume of this gas. It is also slightly soluble in water, and considerably so in ether.

Ethyl, once isolated, cannot be made to re-combine with any element at ordinary temperatures. In this respect it also resembles hydrogen, but in the case of this element the application of a red heat serves to make it combine with most negative elements, as oxygen, sulphur, chlorine, &c.: but a less degree of heat applied to ethyl utterly decomposes this radical, and hence all attempts to re-combine ethyl have hitherto failed.

Although no compound of ethyl can be directly formed from the radical, yet a large number of such compounds may be obtained from its hydrated oxide $\left(\text{alcohol } \left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2\right)$, and we will now describe some of the most important of these compounds.

Hydride of ethyl (C_4H_5,H). Obtained by heating together equal parts of water and of iodide of ethyl with granulated zinc, for a couple of hours, in a hermetically sealed tube or digester [DIGESTER], at a temperature of about 330° Fahr. The following equation represents the decomposition that takes place:—

$$\underbrace{C_4H_5, I}_{\text{Iodide of ethyl.}} + \underbrace{Zn_2}_{\text{Zinc.}} + \underbrace{HO}_{\text{Water.}} = \underbrace{ZnI}_{\text{Iodide of zinc.}} + \underbrace{ZnO}_{\text{Oxide of zinc.}} + \underbrace{C_4H_5, H}_{\text{Hydride of ethyl.}}$$

It may also be obtained by decomposing moist cyanide of ethyl with potassium, as noticed under CYANETHINE.

Hydride of ethyl is a permanent gas, insoluble in water, and may therefore be collected by opening the vessel in which it has been made under a bell jar in the pneumatic trough. It is colourless, odourless, and tasteless. Sp. gr. 1·075. Alcohol absorbs rather more than its own volume of this gas. Chlorine acts upon it, replacing the hydrogen in it, to a greater or less extent according as the mixture of the gases is exposed to the direct rays of the sun or merely to diffused daylight.

Oxide of ethyl; Ether; Æther; Ethylic ether; Vinic ether; Sulphuric ether $\left(\left\{\begin{matrix}C_4H_5O\\C_4H_5O\end{matrix}\right\}\right)$.

This compound was first called ether in 1730 by Frobenius. [FROBEN, in BIOG. DIV.] It was known, however, long prior to that date. Conrad Gesner, in a work published in 1552, transcribed the process of making it from the dispensatory of Valerius Cordus, and gives to it the name *Oleum Vitrioli dulce*. It is also said to have been known to Raymond Lully, who lived in the 13th century. During the last fifty years it has been made the subject of research by several eminent chemists, and the theory put forward by Berzelius that it was the oxide of a (then) hypothetical radical ethyl, has since been established by Liebig, Williamson, and others.

The best method of preparing ether is that known as Boullay's Continuous Process. It consists of an arrangement by which a small stream of alcohol (sp. gr. 0·830) supplied from a reservoir is made to flow into a vessel containing equal volumes of alcohol and sulphuric acid, the latter mixture being maintained at a temperature between 284° and 290° Fahr. The alcohol is then rapidly decomposed into ether and water, which distil off in vapour, and must be condensed in a well-cooled refrigerating apparatus. This process may be continued without interruption by means of some such arrangement of apparatus as that figured under CONDENSER (the alcohol supply-tube passing through the cork of the flask there represented), until full thirty times the weight of the quantity of alcohol first mixed with the sulphuric acid has been etherified.

The ether thus obtained may be purified by agitating with an equal bulk of water containing $\frac{1}{18}$th its weight of carbonate of potash in solution. The water dissolves out any alcohol that may have distilled over unchanged, and the carbonate of potash neutralises sulphurous acid which is occasionally formed in small quantity from decomposition of a little of the sulphuric acid. The ether, however, still contains in solution some of the water with which it has been agitated: this may, if necessary, be removed by digesting some pieces of chloride of calcium, or quicklime, in it for a day or two, and then rectifying by the heat of a water-bath, and condensing by an ice-cooled refrigeratory. For some economical methods of condensing and purifying ether on the large scale, see article 'Ether' in Muspratt's 'Chemistry as applied to Arts and Manufactures.'

The decomposition that occurs during the process above described is usually explained in the following manner: Sulphethylic or sulphovinic acid and water, are first formed from one equivalent of alcohol and two equivalents of sulphuric acid, thus:—

$$\underbrace{\left.\begin{matrix}H\\H\end{matrix}\right\}O_2, S_2O_6}_{\text{Double equiv. of sulphuric acid.}} + \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Alcohol.}} = \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2, S_2O_6}_{\text{Sulphovinic acid.}} + \underbrace{\left.\begin{matrix}H\\H\end{matrix}\right\}O_2}_{\text{Water.}}$$

The sulphovinic acid is then decomposed on coming into contact with another equivalent of alcohol, its ethyl being replaced by the equivalent of hydrogen turned out from the second equivalent of alcohol, and sulphuric acid and ether formed:—

$$\underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2, S_2O_6}_{\text{Sulphovinic acid.}} + \underbrace{\left.\begin{matrix}C_4H_5\\H\end{matrix}\right\}O_2}_{\text{Alcohol.}} = \underbrace{\left.\begin{matrix}C_4H_5\\C_4H_5\end{matrix}\right\}O_2}_{\text{Ether.}} + \underbrace{\left.\begin{matrix}H\\H\end{matrix}\right\}O_2, S_2O_6}_{\text{Sulphuric acid.}}$$

The sulphuric acid thus set at liberty is free to commence the same round of re-actions over again.

Other substances besides sulphuric acid are capable of etherifying alcohol, but they are of no practical importance.

Pure ether is a colourless, limpid, mobile liquid. It is a powerful refractor of light, has a peculiarly penetrating odour, and a taste at first hot but afterwards cooling. It is neutral to test-paper; has a sp. gr. of 0·724 at 55° Fahr.; boiling point, 94·8° Fahr.; and on being cooled to —24° Fahr. crystallises in brilliant white plates. Ether is exceedingly inflammable; and as its vapour is heavy (2·565), great caution is necessary that the operation of pouring it from one vessel to another be not performed in the vicinity of a naked flame. Moreover, the vapour forms, with certain proportions of atmospheric air, a mixture that burns with explosive rapidity. Ether is miscible with alcohol in all portions. When agitated with water, each liquid dissolves its companion to the extent of one-eighth of its own bulk.

Ether is acted upon by most of the energetic chemical reagents, as will be abundantly seen on looking over the processes for the production of many of the ethyl compounds that follow. It is of considerable value as a medicinal agent producing stimulating and intoxicating effects when taken into the stomach. It was much used as an anæsthetic a few years ago, but for that purpose is now quite superseded by chloroform. [ANÆSTHETICS.]

Ether, like potash, soda, &c., unites with the oxyacids, forming many interesting and useful compounds. The method of preparing the principal of these will be found described under the respective acids. Many of them may be formed by acting upon the potash or soda-salt of the acid, with a mixture of alcohol and sulphuric acid, that is, with sulphovinic acid. The formulæ of some of these ETHEREAL SALTS, and their general relation to other ethyl compounds, will be shown at the latter part of this article.

Acetic ether has an agreeable odour somewhat like that of apples. It occurs in several wines. *Angelic ether* smells like rotten apples. *Butyric ether* is used as essence of pine-apples; *caproic* and *caprylic ethers* having a similar odour. *Formic ether* in taste and smell is like peach kernels. *Nitrous ether*, dissolved in alcohol, is the *sweet spirit of nitre* of pharmacy; the *spiritus etheris nitrosi* of the London pharmacopœia. *Œnanthic ether* causes the peculiar vinous odour of most wines.

Hydrated oxide of ethyl ($C_4H_6O_2 = C_4H_5O, HO$), or *Alcohol*, has already been fully treated of. [ALCOHOL.]

Chlorine derivatives of oxide of ethyl. Chlorine acts upon ether, giving rise to substitution compounds in which the hydrogen is more or less replaced. The following formulæ will conveniently show their relation to ether:—

Oxide of chlorethyl	$C_4\left\{\begin{matrix}H_4\\Cl\end{matrix}\right\}O$
Oxide of bichlorethyl	$C_4\left\{\begin{matrix}H_3\\Cl_2\end{matrix}\right\}O$
Oxide of perchlorethyl	C_4Cl_5, O
Oxide of perchlorbromethyl . . .	$C_4\left\{\begin{matrix}Cl_3\\Br_2\end{matrix}\right\}O$

Sulphides of ethyl. There are three of these, namely:—

1. Mercaptan (sulphydrate of ethyl, or ethylsulphydric acid)	$\left\{\begin{matrix}C_4H_5S\\HS\end{matrix}\right\}$
2. Sulphide of ethyl	$\left.\begin{matrix}C_4H_5S\\C_4H_5S\end{matrix}\right\}$
3. Bisulphide of ethyl	$\left.\begin{matrix}C_4H_5S_2\\C_4H_5S_2\end{matrix}\right\}$

1. Mercaptan may be produced in several ways. The following is the most expeditious. Sulphovinate of potash is added to excess of caustic potash that has previously been saturated with sulphuretted hydrogen, and the whole submitted to distillation. An exceedingly well cooled condenser must be used in the operation.

$$\underbrace{KO, C_4H_5O, S_2O_6}_{\text{Sulphovinate of potash.}} + \underbrace{KS, HS}_{\text{Sulphydrate of potassium.}} = \underbrace{C_4H_5S, HS}_{\text{Mercaptan.}} + \underbrace{2(KO, SO_3)}_{\text{Sulphate of potash.}}$$

Mercaptan is a colourless, transparent, mobile liquid of an excessively disgusting smell. Its sp. gr. at 70° Fahr. is 0·835. Vapour-density 2·11. Boiling point 142°–145°. Burns readily in air with a blue flame; is slightly soluble in water, readily so in alcohol or ether. Its volatility is such that when a glass rod moistened with it is passed quickly through the air, a temperature (−8° Fahr.) is produced sufficiently low to solidify what may be remaining on the rod.

Mercaptan forms compounds with the metals called *mercaptides* or *ethylsulphides*. They are monobasic. The potash and soda salts may be obtained by simply dropping potassium or sodium into mercaptan, an equivalent of metal replacing one equivalent of hydrogen from one of mercaptan. An alcoholic solution of mercaptan acts with great energy upon oxide of mercury (hence the name mercaptan, from *mercurium captans*), and forms white, crystalline, odourless, *mercaptide of mercury* (HgS, C_4H_5S). The gold, silver, and copper salts are white; those of platinum and lead are yellow. Mercaptan may be regarded as alcohol in which the oxygen is replaced by sulphur.

2. Sulphide of ethyl, or sulphydric ether, is readily prepared on passing a current of chloride of ethyl into an alcoholic solution of protosulphide of potassium to saturation, and then distilling the mixture. It is a colourless liquid, odour almost as unpleasant as mercaptan; sp. gr. 0·825, vapour-density 3·1, boiling point 163·4°. It forms combinations with some of the metallic chlorides.

3. Bisulphide of ethyl. Obtained on distilling three parts of sulphovinate of potash with two of pentasulphide of potassium. It is colourless, has a disagreeable odour, is slightly soluble in water, and very soluble in alcohol or ether. Its sp. gr. is nearly that of water, boiling point 304°, vapour-density 4·27.

Selenides of ethyl are two in number:

1. Ethylselenhydric acid	$\left.\begin{matrix}C_4H_5Se\\H\ Se\end{matrix}\right\}$
2. Selenide of ethyl	$\left.\begin{matrix}C_4H_5Se\\C_4H_5Se\end{matrix}\right\}$

1. Ethylselenhydric acid is a yellow fetid liquid, resulting from the distillation of a mixture of sulphovinate of lime and selenhydrate of potash. It is heavier than water; boiling point about 212° Fahr.

2. Selenide of ethyl, or selenhydric ether, is a clear yellow liquid heavier than water. It is formed on distilling selenide of potassium with sulphethylate of potash. It combines with chlorine, bromine, iodine, &c., forming compounds of much theoretical but little general interest.

Telluride of ethyl $\left.\begin{matrix}C_4H_5Te\\C_4H_5Te\end{matrix}\right\}$ comports itself like selenide of ethyl. It may be obtained by distilling telluride of potassium with sulphovinate of potash. It has a yellowish-red colour, persistent disagreeable odour, boiling point about 212° Fahr., and is rapidly altered in contact with air.

Fluoride of ethyl (C_4H_5, F) is a mobile very volatile liquid, having an odour somewhat resembling that of horseradish.

Chloride of ethyl (C_4H_5Cl.), *hydrochloric ether*, may be readily prepared by distilling a mixture of three parts of strong sulphuric acid, two of alcohol, and four of fused chloride of sodium. Two condensers must be used in the operation, the first kept at a temperature of about 70° Fahr., from which water and alcohol will be collected; the second, cooled with ice, or a freezing mixture, in which the chloride of ethyl will collect. It may be rectified over chloride of calcium.

Chloride of ethyl has a powerfully aromatic, faintly alliaceous odour. Its sp. gr. at 41° Fahr., is 0·874. Vapour-density, 2·219. Boiling point, 52° Fahr. It burns with a bright flame edged with green, is very slightly soluble in water, but freely so in alcohol. It is a solvent of sulphur, phosphorus, fats, oils, and resins. Its vapour passed through a red hot porcelain tube is decomposed into olefiant gas (C_4H_4) and hydrochloric acid.

Chlorine derivatives of chloride of ethyl. Chlorine acts upon chloride of ethyl, heat is evolved, and hydrochloric acid produced by the union of part of the chlorine with hydrogen that is displaced by another part of the chlorine. In this way an interesting series of substitution-compounds is obtained, in which the five equivalents of hydrogen in chloride of ethyl are successively replaced by equivalents of chlorine. The following list of these compounds, with their formulæ, will at once show the relation they bear to chloride of ethyl and to each other:—

Chloride of ethyl	$C_4\ H_5\ Cl$
„ chlorethyl	$C_4\left\{\begin{matrix}H_4\\Cl\end{matrix}\right\}Cl$
„ bichlorethyl . . .	$C_4\left\{\begin{matrix}H_3\\Cl_2\end{matrix}\right\}Cl$
„ trichlorethyl	$C_4\left\{\begin{matrix}H_2\\Cl_3\end{matrix}\right\}Cl$
„ quadrichlorethyl . . .	$C_4\left\{\begin{matrix}H\\Cl_4\end{matrix}\right\}Cl$
„ perchlorethyl	$C_4\ Cl_5\ Cl$

The last is identical with the sesquichloride of carbon (C_4Cl_6). [CHLORINE; CARBON.]

Bromide of ethyl, or *hydrobromic ether* (C_4H_5Br), is made much in the same way as the next compound—iodide of ethyl—bromine being used instead of iodine. It is a colourless liquid of penetrating ethereal odour and taste. Its sp. gr. is 1·4733 at 32° Fahr. Vapour-density, 3·754. Boiling point, 106°. It is almost insoluble in water, but miscible in all proportions with alcohol or ether.

Iodide of ethyl (C_4H_5I), *hydriodic ether.* To 100 parts of alcohol contained in a capacious flask there are alternately added, by small portions at a time, 60 parts of iodine and 20 parts of phosphorus. If the action becomes violent during the operation, a cork should be put into the neck of the flask, and the whole plunged beneath the surface of cold water. The mixture is finally distilled, care being taken that a slight excess of iodine is present, which will be the case if the mixture keeps of a brown colour. The condensed iodide of ethyl should be allowed to flow into a receiver containing water, at the bottom of which it will collect. After separating the water, the iodide of ethyl may be obtained in a perfectly pure state, on rectifying from a few pieces of chloride of calcium. In the above process the iodine and phosphorus first combine to form iodide of phosphorus; this, with the elements of water, is then decomposed into phosphorous acid and hydriodic acid, and the latter reacting upon alchohol produces iodide of ethyl and water.

Iodide of ethyl is a neutral liquid, colourless when pure, but becoming brown by the action of air and light, from liberation of iodine. Its odour is ethereal and penetrating. It is exceedingly heavy, having at 61° Fahr., a sp. gr. of 1·9464. Its boiling point is 162°·2 Fahr. Vapour-density 5·475. It is scarcely at all soluble in water, but very soluble in alcohol. It burns with difficulty. Heated with water in a sealed tube to 302° Fahr., it is decomposed into ether and hydriodic acid; if oxide of silver be present, then alcohol and iodide of silver are formed.

Nitrides of ethyl. [ORGANIC BASES.]

Cyanide of ethyl ($C_4H_5N = C_4H_5Cy$), *hydrocyanic ether, metacetonitrile, propionitrile.* Equal weights of sulphovinate of potash and of cyanide of potassium are powdered, intimately mixed, and heated together in a retort; the distillate, which has a disagreeable alliaceous odour should be washed with water, and rectified over anhydrous phosphoric acid. Thus obtained, it is a colourless liquid of agreeable odour, sp. gr. 0·78. Boiling point 179°·6 Fahr. It is said to be excessively poisonous, but of this there is some doubt, as, prepared by the above process, it always contains hydrocyanic acid, &c. A boiling solution of potash converts it into propionate of potash with disengagement of ammonia.

$$\underbrace{C_4H_5,\ C_2N}_{\text{Cyanide of ethyl.}} + KO,\ HO + 2HO = \underbrace{KO,\ C_6H_5O_3}_{\text{Propionate of potash.}} + NH_3$$

For the action of potassium on cyanide of ethyl, see CYANETHINE.

Ethide of sodium (C_4H_5, Na), *sodium ethyl.* Mr. Wanklyn has recently discovered a combination of this compound with two equivalents of zinc-ethyl ($NaC_4H_5 + 2\,ZnC_4H_5$). It is formed by acting upon zinc-ethyl with sodium, when metallic zinc is precipitated, and sodium dissolved, equivalent for equivalent. The double compound may be obtained in crystals from solution in zinc-ethyl. Heat decomposes the crystals, gas is evolved, and the residue consists of sodium and zinc, without any admixture of carbon. The action of carbonic acid on the crystals is interesting, heat is evolved, zinc-ethyl distils off, and there remains a white residue of propionate of soda. The re-action is expressed in the following equation:—

$$C_2O_4 + Na,\ C_4H_5 = \left.\begin{matrix}C_2O_2C_4H_5\\Na\end{matrix}\right\}O_2$$

Ethide of potassium (C_4H_5Na), *potassium ethyl*, is obtained in the same manner, and, so far as at present ascertained, closely resembles the ethide of sodium just described.

Ethide of zinc (C_4H_5Zn), *zinc-ethyl.* Obtained by heating together in a sealed glass tube, or digester, equal volumes of iodide of ethyl and ether, both perfectly anhydrous, and a quantity of well-dried granulated zinc, equal to about twice the weight of the iodide of ethyl. A heat of about 250° Fahr. should be kept up for fifteen or twenty hours. When cool the vessel may be opened, and the zinc-ethyl distilled off from the residue of iodide of zinc, contact with air being avoided as much as possible.

Zinc-ethyl is a colourless, transparent, mobile liquid. Boiling point 244° Fahr. Sp. gr. at 64° Fahr. 1·182. Vapour-density, 4·259. Its affinity for oxygen is so intense as to render it spontaneously inflammable in the air, when it burns with a brilliant blue flame, fringed with green, and forms dense white clouds of oxide of zinc. Allowed to oxidise slowly, a white substance results containing C_4H_5O, Zn O, the *ethylate of zinc* or *zinc alcohol.* [ORGANOMETALLIC BODIES.]

Ethide of tin (C_4H_5Sn), *stanethyl.* Formed by the re-action of granulated tin and iodide of ethyl with the aid of heat or light. By double decomposition of the iodide of stanethyl thus produced, an oxide, chloride, sulphide, &c., may be formed, and the stanethyl itself isolated by the action of metallic zinc on the chloride of stanethyl.

Stanethyl is a yellow oily liquid, decomposed by a heat of about 300° Fahr.

Other compounds of ethyl and tin also exist. [ORGANOMETALLIC BODIES.]

Terethide of antimony ($3C_4H_5$, Sb), *stibethyl.* Obtained by acting upon iodide of ethyl with an alloy of antimony and potassium. It is a heavy limpid liquid, has a powerful odour of onions, and is spontaneously inflammable. Sp. gr. 1·324, vapour-density 7·438, boiling point 317°. It forms salts with oxygen, iodine, sulphur, &c.

Binethide of arsenic ($2C_4H_5$, As), *arseniodiethyl*, and its compounds are very similar to cacodyl, the bimethide of arsenic. [CACODYL.]

Terethide of arsenic ($3C_4H_5$, As), *arseniotriethyl*, is the chief product of the action of iodide of ethyl on an alloy of arsenic and sodium. It is scarcely spontaneously inflammable. Its compounds have a very close analogy to those of terethide of antimony.

Terethide of bismuth ($3C_4H_5$, Bi), *bistriethyl*, results from the action of iodide of ethyl upon an alloy of bismuth and potassium. It is a yellowish liquid of disagreeable odour. Sp. gr. 1·82. It combines with the metalloids.

Ethide of mercury, mercuryethyl, hydrargethyl, has been obtained in combination, and several of the salts described.

Ethide of lead, plumbethyl, forms in combination salts that correspond to binoxide of lead (Pb_2O_4). The oxide of plumbethyl contains $Pb_2\,(C_4H_5)_2O$ and the chloride $Pb_2\,(C_4H_5)_3Cl$.

Ethide of cadmium (C_4H_5, Cd), *cadmium-ethyl*, may be formed by a process similar to that for making zinc-ethyl. It has not yet been procured in a state of perfect purity.

The following are the names and formulæ of the remaining more important compounds of ethyl. The preparation and properties of the most interesting of them will be found described in the article treating of the several bodies with which the ethyl is combined.

Ethyl-acetamide	$N\left\{\begin{matrix}C_4H_3O_2\\C_4H_5\\H\end{matrix}\right.$
Ethyl-diacetamide	$N\left\{\begin{matrix}C_4H_3O_2\\C_4H_3O_2\\C_4H_5\end{matrix}\right.$

Ethylamine	$N\left\{\begin{matrix}C_4H_5\\H\\H\end{matrix}\right.$
Diethylamine	$N\left\{\begin{matrix}C_4H_5\\C_4H_5\\H\end{matrix}\right.$
Triethylamine	$N\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right.$
Tetrethylammonium hyd. ox.	$N\left\{\begin{matrix}C_4H_5\\C_4H_5\\C_4H_5\\C_4H_5\end{matrix}\right\}O, HO$
Ethyl-amyl	$\left\{\begin{matrix}C_4H_5\\C_{10}H_{11}\end{matrix}\right.$
Ethylaniline	$N\left\{\begin{matrix}C_{12}H_5\\C_4H_5\\H\end{matrix}\right.$
Diethylaniline	$N\left\{\begin{matrix}C_{12}H_5\\C_4H_5\\C_4H_5\end{matrix}\right.$
Ethylchloraniline	$N\left\{\begin{matrix}C_{12}H_4Cl\\C_4H_5\\H\end{matrix}\right.$
Diethylchloraniline	$N\left\{\begin{matrix}C_{12}H_4Cl\\C_4H_5\\C_4H_5\end{matrix}\right.$
Ethylbromaniline	$N\left\{\begin{matrix}C_{12}H_4Br\\C_4H_5\\H\end{matrix}\right.$
Ethylnitraniline	$N\left\{\begin{matrix}C_{12}H_4NO_4\\C_4H_5\\H\end{matrix}\right.$
Ethylcyaniline	$N\left\{\begin{matrix}C_{12}H_4Cy\\C_4H_5\\H\end{matrix}\right.$
Ethylamylaniline	$N\left\{\begin{matrix}C_{12}H_5\\C_4H_5\\C_{10}H_{11}\end{matrix}\right.$
Ethylcarbamate of ethyl	$\left.\begin{matrix}NH(C_4H_5)(CO)_2O\\C_4H_5, O\end{matrix}\right\}$
Ethylcodeine	$C_{36}\left\{\begin{matrix}H_{20}\\C_4H_5\end{matrix}\right\}NO_6$
Ethylconine	$N(C_{16}H_{14})(C_4H_5)$
Ethylformiamide	$N\left\{\begin{matrix}C_2HO_2\\C_4H_5\\H\end{matrix}\right.$
Ethylmorphine	$C_{34}\left\{\begin{matrix}H_{18}\\C_4H_5\end{matrix}\right\}NO_6$
Ethylnarcotine	$C_{42}\left\{\begin{matrix}H_{20}\\C_4H_5\end{matrix}\right\}NO_{14}$
Ethylnicotine	$NC_{10}H_7(C_4H_5)$
Ethylnitrophenidine	$C_{16}H_{10}(NO_4)NO_2$
Ethylpicoline	$C_{12}H_7(C_4H_5)N$
Ethylpiperidine	$NC_{10}H_{10}(C_4H_5)$
Ethylpyridine	$NC_{10}H_5(C_4H_5)$
Ethylquinine	$C_{40}H_{24}(C_4H_5)N_2O_4$
Ethylstrychnine	$C_{42}H_{21}(C_4H_5)N_2O_4$
Ethylthiosinnamine	$\left.\begin{matrix}NH_2(C_4H_5)(C_6H_5)S\\Cy\ S\end{matrix}\right\}$
Ethyltoluidine	$N\left\{\begin{matrix}C_{14}H_7\\C_4H_5\\H\end{matrix}\right.$
Diethyltoluidine.	$N\left\{\begin{matrix}C_{14}H_7\\C_4H_5\\C_4H_5\end{matrix}\right.$
Ethyl-urea	$N_2\left\{\begin{matrix}C_2O_2\\C_4H_5\\H_3\end{matrix}\right.$
Ethylmethylurea	$N_2\left\{\begin{matrix}C_2O_2\\C_4H_5\\C_2H_3\\H_2\end{matrix}\right.$
Tetrethylurea	$N_2\left\{\begin{matrix}C_2O_2\\2(C_4H_5)\\2(C_4H_5)\end{matrix}\right.$
Ethyl-urethane (carbamate of ethyl).	[Carbamic Acid.]

Acids containing Ethyl.

Ethylamylcitric acid	$C_{12}H_5(C_4H_5)(C_{10}H_{11})O_{14}$
Ethylcamphoric acid	$C_{20}H_{15}(C_4H_5)O_8$
Ethylcarbamic acid	$\left.\begin{matrix}NH(C_4H_5)(CO)_2O\\HO\end{matrix}\right\}$
Ethylcarbonic acid	$C_2O_4\left\{\begin{matrix}C_4H_5O\\HO\end{matrix}\right.$
Ethylchloroplatinic acid	$C_4H_4Pt, PtCl_2$
Ethylcomenic acid	$C_{12}H_3(C_4H_5)O_{10}$
Ethylhemipinic acid	$C_{20}H_9(C_4H_5)O_{12}$
Ethylmalic acid	$C_8H_5(C_4H_5)O_{10}$
Ethylmeconic acid	$C_{14}H_3(C_4H_5)O_{14}$
Diethylmeconic acid	$C_{14}H_2(C_4H_5)_2O_{14}$
Ethylmellic acid	$C_8H(C_4H_5)O_8$
Ethylmucic acid	$C_{12}H_9(C_4H_5)O_{16}$
Ethylotrithionic acid	$S_3(C_4H_5)O_5$
Ethyloxalic acid	$C_4O_6\left\{\begin{matrix}C_4H_5O\\H\ O\end{matrix}\right.$
Ethyloxamic acid	$\left.\begin{matrix}NH(C_4H_5)(C_2O_2)_2O\\H\ O\end{matrix}\right\}$
Ethylparatartric acid	$C_8H_5(C_4H_5)O_{12}$
Ethylphosphorous acid	$C_4H_5O, 2HO, PO_3$
Ethylphosphoric acid	$\left.\begin{matrix}C_4H_5O\\H\ O\\H\ O\end{matrix}\right\}PO_5$
Diethylphosphoric acid	$\left.\begin{matrix}C_4H_5O\\C_4H_5O\\H\ O\end{matrix}\right\}PO_5$
Ethylsulphophosphoric acid	$\left.\begin{matrix}C_4H_5O\\HS\\HS\end{matrix}\right\}PO_5$
Ethylsulphocarbonic acid	$C_2O_4\left\{\begin{matrix}C_4H_5S\\H\ S\end{matrix}\right.$
Ethyldisulphocarbonic acid	$C_2S_4\left\{\begin{matrix}C_4H_5O\\H\ O\end{matrix}\right.$
Ethyltrisulphocarbovinic acid	$C_2S_4\left\{\begin{matrix}C_4H_5S\\H\ S\end{matrix}\right.$
Ethylsulphurous acid	$\left.\begin{matrix}C_4H_5O\\H\ O\end{matrix}\right\}S_2O_4$
Ethylsulphuric acid	$\left.\begin{matrix}C_4H_5O\\H\ O\end{matrix}\right\}S_2O_6$
Ethyltartric acid	$C_8H_5(C_4H_5)O_{12}$

Ethereal Salts—Compounds containing oxide of ethyl united with an acid. [Ethers.]

Acetic ether	$C_4H_5O, C_4H_3O_3$
Aconitic ether	$3C_4H_5O, C_{12}H_3O_9$
Allophanic ether	$C_4H_5O, C_4H_3N_2O_5$
Angelic ether	$C_4H_5O, C_{10}H_7O_3$
Anisic ether	$C_4H_5O, C_{10}H_7O_5$
Benzoic ether	$C_4H_5O, C_{14}H_5O_3$
Boracic ether	$3C_4H_5O, BO_3$
Butylic ether	C_4H_5O, C_8H_9O
Butyric ether	$C_4H_5O, C_8H_7O_3$
Camphoric ether	$2C_4H_5O, C_{20}H_{14}O_6$
Capric ether (rutic ether)	
Caproic ether	$C_4H_5O, C_{12}H_{11}O_3$
Caprylic ether	$C_4H_5O, C_{16}H_{15}O_3$
Carbamic ether	$C_4H_5O, C_2H_2NO_3$
Carbanilic ether	$C_4H_5O, C_{14}H_6NO_3$
Carbonic ether	$2C_4H_5O, C_2O_4$
Cerotic ether	$C_4H_5O, C_{54}H_{53}O_3$
Chloracetic ether	$C_4H_5O, C_4Cl_3O_3$
Chlorocarbonic ether	C_4H_5Cl, C_2O_4
Cinnamic ether	$C_4H_5O, C_{18}H_7O_3$
Citraconic ether	$C_4H_5O, C_{14}H_9O_7$
Citric ether	$3C_4H_5O, C_{12}H_5O_{11}$
Cyanic ether	C_4H_5O, C_2NO
Cyanuric ether	$3C_4H_5O, C_6N_3O_3$
Elaïdic ether	$C_4H_5O, C_{36}H_{33}O_3$
Formic ether	C_4H_5O, C_2HO_3
Fumaric ether	$C_4H_5O, C_8H_2O_7$
Hypogeic ether	$C_4H_5O, C_{32}H_{29}O_3$
Isocetic ether	$C_4H_5O, C_{30}H_{29}O_3$
Itaconic ether	$C_4H_5O, C_{10}H_4O_7$
Lactic ether	$2C_4H_5O, C_{12}H_{10}O_{10}$
Lecanoric ether (orsellesic ether)	
Margaric ether	$C_4H_5O, C_{34}H_{33}O_3$
Mesaconic ether	$C_4H_5O, C_{14}H_9O_7$
Mucic ether	$2C_4H_5O, C_{12}H_8O_{14}$
Myristic ether	$C_4H_5O, C_{28}H_{27}O_3$
Nitric ether	C_4H_5O, NO_5
Nitrous ether	C_4H_5O, NO_3
Œnanthic ether	$C_4H_5O, C_{14}H_{13}O_3$
Œnanthylic ether	$C_4H_5O, C_{14}H_{13}O_3$
Oleic ether	$C_4H_5O, C_{36}H_{33}O_3$
Opianic ether	$C_4H_5O, C_{20}H_9O_9$

Orsellesic ether	$C_4H_5O, C_{16}H_7O_7$
Oxalic ether	$2C_4H_5O, C_4O_6$
Oxamic ether	$C_4H_5O, C_4H_2NO_5$
Palmitic ether	$C_4H_5O, C_{32}H_{31}O_3$
Pelargonic ether	$C_4H_5O, C_{18}H_{17}O_3$
Perchloric ether	C_4H_5O, ClO_7
Phenic ether	$C_4H_5O, C_{12}H_5O$
Phosphoric ether	$3C_4H_5O, PO_5$
Pyrophosphoric ether	$4C_4H_5O, P_2O_{10}$
Phosphorous ether	$3C_4H_5O, PO_3$
Propionic ether	$C_4H_5O, C_6H_5O_3$
Pyrocitric ether (itaconic ether)	
Pyromucic ether	$C_4H_5O, C_{10}H_3O_5$
Pyrotartric ether	$2C_4H_5O, C_{10}H_6O_6$
Quinic ether	$C_4H_5O, C_{14}H_{11}O_{11}$
Rutic ether	$C_4H_5O, C_{20}H_{19}O_3$
Salicylic ether	$C_4H_5O, C_{14}H_5O_5$
Sebacic ether	$2C_4H_5O, C_{20}H_{16}O_6$
Silicic ether	C_4H_5O, SiO_2
Disilicic ether	$2C_4H_5O, SiO_2$
Suberic ether	$2C_4H_5O, C_{16}H_{12}O_6$
Succinic ether	$2C_4H_5O, C_8H_4O_6$
Sulphocarbonic ether	$2C_4H_5S, C_2O_4$
Disulphocarbonic ether	$2C_4H_5O, C_2S_4$
Trisulphocarbonic ether	$2C_4H_5S, C_2S_4$
Sulphocyanhydric ether	C_4H_5S, C_2NS
Sulphuric ether (true)	C_4H_5O, S_2O_6
Tartaric ether	$2C_4H_5O, C_8H_4O_{10}$
Toluic ether	$C_4H_5O, C_{16}H_7O_3$
Valeric ether	$C_4H_5O, C_{10}H_9O_3$
Xanthic ether (disulphocarbonic ether).	

Detailed information concerning the whole of the compounds of ethyl (except those discovered since the year 1856), will be found in Gerhardt's 'Traité de Chimie Organique.'

ETHYL, used in chemical nomenclature as a prefix, is employed to denote the presence of ethyl in the compound to which the name is applied; thus *ethyl-camphoric acid* denotes camphoric acid containing ethyl. All such compounds will be found mentioned or described under ETHYL.

ETHYLAMINE. [ORGANIC BASES.]

ETHYLENE. (C_4H_4). *Olefiant gas Elayl.* Ethylene is one of the illuminating constituents of coal gas. It is also a common gaseous product of the destructive distillation of other organic substances besides coal; resins, fats, oils, caoutchouc, &c., all yield ethylene when heated in close vessels. When however this gas is required in a state of purity, it is always produced by heating together one part of alcohol and six or seven parts of concentrated sulphuric acid, and conducting it first through a Woulf's bottle containing milk of lime to remove any sulphurous acid, and then through a bottle containing strong sulphuric acid to absorb vapours of alcohol and ether. The reaction by which the olefiant gas is produced, simply consists in a dehydration of the alcohol by the acid, thus:—

$$\underbrace{C_4H_6O_2}_{\text{Alcohol.}} = \underbrace{C_4H_4}_{\text{Olefiant gas.}} + \underbrace{2HO}_{\text{Water.}}$$

but other decompositions occur simultaneously, for the mixture in the generating vessel gradually darkens in colour, and a black gelatinous mass is the final product.

Ethylene is colourless, tasteless, and irrespirable, has a peculiar odour, is of sp. gr. 0·9784, and may be liquified by the combined aid of great pressure and intense cold. It is almost insoluble in water, and but slightly soluble in strong sulphuric acid. Anhydrous sulphuric acid absorbs it in large quantity. It is inflammable, burning with a highly luminous flame. Mixed with twice its volume of chlorine and the mixture ignited, rapid combustion ensues, hydrochloric acid gas is evolved, and a dense cloud of carbon at the same time produced.

Ethylene has the property of combining directly with two equivalents of chlorine or of bromine, iodine, and sulphur, forming the compounds—

Chloride of ethylene	$C_4H_4Cl_2$
Bromide "	$C_4H_4Br_2$
Iodide "	$C_4H_4I_2$
Sulphide "	$C_4H_4S_2$

and recently Dr. Guthrie has described combinations of ethylene with dichloride of sulphur (ClS_2), and with protochloride of sulphur (ClS); the names and formulæ of the compounds being—

Bisulphochloride of ethylene	C_4H_4, S_2Cl
Bichlorosulphide "	C_4H_4, S_2Cl_2

Derivatives of ethylene.—The four equivalents of hydrogen in ethylene may be wholly or in part replaced by chlorine, and four distinct compounds thus obtained. Or they may be replaced by bromine, and to a certain extent by iodine. The names and formulæ of these substitution compounds are—

Ethylene = C_4H_4

Chlorethylene	C_4H_3Cl	Bromethylene	C_4H_3Br
Bichlorethylene	$O_4H_2Cl_2$	Bitromethylene	$C_4H_2Br_2$
Trichlorethylene	$C_4H\ Cl_3$	Tribromethylene	$C_4H\ Br_3$
Perchlorethylene	$C_4\ \ Cl_4$	Perbromethylene	$C_4\ \ Br_3$
Iod-ethylene	C_4H_3I		

Moreover, as with ethylene itself, so with each of the bodies just enumerated, two equivalents of chlorine or of bromine can unite and form a second series of compounds. Such a compound is the chloride of perchlorethylene (C_4Cl_4, Cl_2), or sesquichloride of carbon (C_4Cl_6), while perchlorethylene itself is the protochloride of carbon (C_4Cl_4). [CARBON, *chlorides of.*]

Ethylene combines with anhydrous sulphuric acid, forming crystals of *anhydrous ethionic acid* ($C_4H_4, 4SO_3$). Cold water converts the latter into *hydrated ethionic acid* ($C_4H_4, 4SO_3, 2HO$), which is by ebullition transformed into *isethionic acid* ($C_4H_4, 2SO_3, 2HO$). Ethionic acid is bibasic, isethionic acid monobasic; they both combine with bases to form salts that are mostly crystalline.

Dutch liquid. Ethylene was discovered by some Dutch chemists in 1795. It was called *olefiant* gas, because when brought into contact with chlorine over water the two combined to form a yellowish *oily* liquid that floated on the surface of the water. This oily chlorine compound has always retained the name of *Dutch liquid*, though its true composition ($C_4H_4Cl_2$, chloride of ethylene, mentioned above) is well known. It was the source of that interesting series of ethylene derivatives already enumerated, and has thus greatly aided the advancement of the now well known chemical doctrine of substitution.

ETRUSCAN ARCHITECTURE. We have no remains of Etruscan temples or other important buildings, but we know from ancient authorities that the Etruscans constructed sumptuous public and private edifices; and we can form some idea of their style from their hypogei or sepulchral monuments, and also from some of their cinerary urns which have representations of temples (Micali, plate 72). Vitruvius, although he lived in an age when Etruscan art had undergone considerable alteration, characterises their buildings as "baricephalæ, humiles, latæ," low, wide, with heavy top ornaments. And this seems to be in keeping with the character of the people, grave, and more fond of internal comfort than of external show. What is now called the Tuscan order appears to have been a sort of rude Doric, which they probably adopted from the Greeks, though varying the type considerably. Vitruvius (iv. 7) gives a description of their temples, which appear to have been circular with a single cella, or rectangular with three cellæ; but they could have been neither large nor splendid: the ornaments, bronzes, and plastic figures seem to have been more elaborate than the structures themselves.

The monuments which serve perhaps to throw most light on the subject of Etruscan architecture are the tombs, and especially those at Castel d'Asso, the Axia of Cicero ('Pro Cæcina,' 7), five miles south-west of Viterbo, where the face of a perpendicular cliff forming one side of the valley is sculptured all along for more than a mile with hundreds of fronts or façades of sepulchral monuments, the vaults themselves being excavated underneath. Similar sculptures on the rock are found at Norchia, about 15 miles south-west of Viterbo. (See Inghirami's *plates*.) But there are other of these tombs, which instead of presenting merely a façade cut out of the rock, are entirely detached, the rock being hewn away all round. Occasionally, where the rock is friable, the tomb is built instead of being hewn out of the solid rock. These monuments, which represent a primitive style of Etruscan building, strike by their resemblance to the Egyptian style in its ruder and simpler form. Plate 62 of Micali represents a monument between Monte Romano and Corneto with projecting architrave and lateral pillars. Another kind of tomb consists of a tumulus of earth, the base of which is surrounded by a podium or supporting wall of masonry. Tumuli of this kind remain in immense numbers about the sites of the ancient cities of Etruria. Some of these tumuli are of vast size. The largest, known as the Cocumella, at Vulci, is 240 feet in diameter, and 50 feet high; but is conjectured to have been originally about 120 feet high. This tumulus has near its centre two large towers, one square and the other round. In all these tombs the principal chamber resembles an abode of the living; and when opened has been found to contain biers or bedsteads, vases, and vessels of various forms, shields, weapons, and other articles, often of exquisite workmanship: it is from these chambers that the Etruscan vases found in such profusion in every museum in Europe, have been obtained. The walls of the chambers in the tombs are sometimes panelled, and generally painted with mythic or festive scenes; and around them are seats, with arm-chairs and foot-stools hewn out of the solid rock. The vaulted roofs of these tombs show that the Etruscans were acquainted with the arch from a very early period. They employed the arch also in their gateways, bridges and aqueducts; and in constructing the Cloaca Maxima and other Roman cloacæ.

In the time of Vitruvius the houses of the wealthy Etruscans had external porticoes or vestibula, in which the crowd of servants and clients remained in waiting. The Atrium is supposed by some to be of Etruscan invention. [Atrium.] But of these, as of their civic buildings, we have no vestiges remaining. Of their theatres there are no remains left. Their amphitheatres have also perished, with the exception of one at Sutri; but as this is hewn out of the rock, it can hardly be regarded as a type of constructed buildings of this class. It is 295 feet by 265, and, except in being more circular, differs little from the Roman amphitheatres—which were no doubt formed on the model of those of Etruria. [Amphitheatre.]

The great constructive skill of the Etruscans was especially shown in their massive walls and fortifications, and in their bridges, sewers, and other works belonging to what we now term civil engineering, rather than to architecture. The walls found in the northern part of Etruria are much more rude and massive than those of the south, where the stones, though large irregular blocks, are rudely squared and laid in horizontal courses; in all parts however the stones are laid without cement. They are of the kind known as Pelasgic, but the term is scarcely specific enough, as it does not distinguish any particular class of these walls; or the walls of any particular locality from other walls of the same kind. Some authors however conceive the Etruscans to have been altogether a Pelasgian tribe, and with them the term means that such walls are of Pelasgic origin.

For fuller and more complete information of what is known respecting Etruscan architecture, see Inghirami, *Monumenti Etruschi* (text and plates, series IV.); Micali, *Antichi Populi Italiani*, and *Monumenti Inediti*; Orioli, *Dei Sepolcrali Edifizi dell' Etruria Media;* Abeken, *Mittel Italien;* Müller, *Etrusker;* Lepsius, *Tyrrhenische Pelasgier in Etrurien;* Dennis, *Cities and Cemeteries of Etruria*; Fergusson, *Handbook of Architecture.*)

ETYMOLOGICUM MAGNUM (*τὸ μέγα ἐτυμολογικόν*), an important vocabulary of the Greek language, of which the author is unknown. Some suppose it was written by a grammarian of the name of Magnus. The idea that it was compiled by Marcus Musurus, the first editor, or the Calliergi, is disproved by the fact that this dictionary is referred to by Eustathius. Sylburg considers it as old as the 10th century: much older it certainly was not; for Theognotus, a writer of the 9th century, is quoted in it. The derivations in this work, like most of those attempted by the Greeks themselves, are based upon no principle, and though in some instances accidentally right, they are generally full of the wildest absurdities, as one might expect from the author being confined to mere guess-work. It is valuable however for containing a great many traditions with regard to the meanings of old or uncommon words, and it often enables the scholar to correct the errors of the corrupt but inestimable lexicon of Hesychius. The edition of Sylburg (1594) is very useful, and has an admirable index: the edition of the Etymologicum Magnum, by Schäfer, Lips., 1816, is a reprint of Sylburg's edition. The edition by Sturz, Lips., 1818, 4to., intituled Etymologicum Græcæ Linguæ Gudianum, &c., is founded on the Codex Gudianus, which is more complete than that on which the edition of Musurus and the others already enumerated are based.

ETYMOLOGY. [Language.]

EUCALYNE ($C_{12}H_{12}O_{12}$). A saccharine substance recently obtained by M. Berthelot in the fermentation of melitose:—

$$\underbrace{2(C_{12}H_{12}O_{12})}_{\text{Melitose.}} = 4CO_2 + \underbrace{2C_4H_6O_2}_{\text{Alcohol.}} + \underbrace{C_{12}H_{12}O_{12}}_{\text{Eucalyne.}}$$

Eucalyne is a syrupy unfermentescible sugar, isomeric with melitose.

EUCHARIST (*εὐχαριστία*, thanksgiving) is a Greek name of the Christian sacramental act otherwise called the Communion, or the Lord's Supper; and, in contradistinction from these appellations, it particularly expresses the idea of thankfully commemorating the mediatorial sacrifice of Christ; or, according to others, the name was assigned in reference to the fact that, when Jesus enjoined the observance of the rite, he gave thanks. [Communion.]

EUCHLORINE. [Chlorine, *oxygen and chlorine.*]

EUCHROÏC ACID ($C_{24}H_4N_2O_{16}$? or $C_8H_3NO_6$). A colourless, crystalline acid, the ammonia salt of which is formed as a bye-product in the preparation of *paramide.* It is distinguished by the production of a beautiful blue colour by contact with metallic zinc. The blue colouring matter thus formed has been termed *euchrone*, but it has not been analysed, on account of the extreme facility with which it decomposes.

EUCHRONE. [Euchroic Acid.]

EUDIOMETER. An instrument employed for the analysis and investigation of gaseous bodies. [Gasometric Analysis.]

EUGENIC ACID. [Caryophillic Acid.]

EUGENIN ($C_{40}H_{24}O_8$?), a substance which deposits spontaneously from the distilled water of cloves; it crystallises in small laminæ, which are colourless, transparent, and pearly, and in time they become yellow. The taste of eugenin is but slight, and the smell much less strong than that of the clove. It is soluble in alcohol and ether in all proportions. By the action of nitric acid, like the oil of cloves, it becomes immediately, even when cold, of a blood-red colour. It appears to be isomeric with Caryophyllic Acid.

EULYTE. A nitrated product derived along with *dyslite*, from the action of nitric acid upon citraconic acid.

EUMENIDES (**Εὐμενίδες**, the kind goddesses), a name given to the Erinyes, or Furies, a set of goddesses whose business it was to avenge murder, perjury, injustice to parents, and the violation of the rites of hospitality. They were also called Semnæ, or "venerable goddesses," both names being significative of the awe with which the Greeks spoke of the dread goddesses. The name Erinys was derived from the old Arcadian word *erinuein* (*ἐρινύειν*), 'to be angry.' (Pausan. viii., 25, 6.) These goddesses appear in the play of Æschylus which bears their name, not only as the instruments of wrath and the pleaders for justice against the matricide, Orestes, but also as the promisers of victory, prosperity, and all sorts of blessings to the Athenian people. Their abode, according to the Homeric notion, was Erebus; and they only come upon earth when recalled thither by the devotion of the accursed to their vengeance. Æschylus describes them as having black bodies, snakes twining about their hair, and eyes which dropped blood. Later they were depicted as rather solemn than terrible in aspect; but they continued to have snakes braided in their hair, and to carry them in their hands. The Eumenides are often represented on vases and elsewhere, but never of the terrible Æschylus type. The site of the temple of the Eumenides at Athens, where their worship possessed a peculiar importance, was the north-east angle of the Areopagus, at its base. "There is a wide, long chasm there, formed by split rocks, through which we enter a gloomy recess. Here is a fountain of very dark water." (Wordsworth's 'Athens and Attica,' p. 79.) The Athenians sacrificed to the Eumenides, among other victims, black sheep: no wine was mixed up with the libations offered to them, but only oil, honey, and water, in three separate libations, out of different vases. (Soph., 'Œd. Col.,' 469, &c.) Of the number of these goddesses we have contradictory accounts; in the play of Æschylus it is pretty certain that there were fifteen in the chorus. By later writers their number is more limited, some making them to be only three in number; and their names Alecto, Megæra, and Tisiphone. (Müller's 'Eumenides,' § 10.) Every question connected with these divinities is accurately and satisfactorily discussed by Müller in the second essay at the end of his edition of the 'Eumenides,' §§ 77–93. See also Böttiger's 'Furienmaske,' and Millin's 'Orestéide.'

EUNUCH (*εὐνοῦχος, eunúchus*, literally, 'one who has the care of a bed'). The Greek word may be considered as descriptive of the functions of those who were made eunuchs, it being usual among the Persians to entrust the care of their wives and daughters to such persons. It does not appear that eunuchs were made by the Greeks; this peculiar species of barbarity was a Persian practice (Herod. vi. 32); though the Greeks sometimes carried on the trade of making eunuchs, whom they sold at Ephesus and Sardis to the Persians for high prices, the Persians considering that eunuchs generally were more trustworthy than other men. (Herod. viii. 105.) Tavernier tells us that in the kingdom of Bootan 20,000 eunuchs were annually made in his time to sell to other nations; and the seraglios of the East are principally served and guarded by them to the present day.

The Christian emperors of Rome forbade the practice of making eunuchs, particularly Constantine; and Justinian imposed a law of retaliation upon such as exercised this inhumanity. In Italy, however, the process of castration was much more recently practised upon children intended to supply the operas and theatres of Europe as singers. The Council of Nice condemned those who from excess of zeal made eunuchs of themselves. Persons so mutilated were not admitted into holy orders. The reader who would know more on this subject may consult the 'Traité des Eunuques,' 12mo, 1707, by M. d'Ancillon.

Certain heretics of the 3rd century bore the name of Eunuchs who had the folly or madness, after the example of Origen, not only to castrate those of their own persuasion, but all whom they could lay hands on. They were also called Valesians, from Valesius, an Arab, who was their chief. (See Epiphanius and Baronius's 'Annals,' under the years 249 and 260.)

EUPATORINE. An alkaloid of unknown composition, contained in the *Eupatorium cannabinum.*

EUPHORBIC ACID. A crystalline acid of unknown composition, said to be contained in the *Euphorbia cyparissias.* Its existence is doubtful.

EUPHORBIUM, improperly called a gum, or gum-resin, since it is entirely destitute of any gum in its composition, is the concrete juice of several species of euphorbia, either exuding naturally or from incisions made in the bark, therefore properly a cereo-resin. Much of the article found in British commerce is obtained from the *Euphorbia Canariensis*, while that which occurs on the Continent is obtained from *Euphorbia officinarum* (Linn.) and *E. antiquorum* (Linn.), and other African species, particularly from an undescribed species, called by the Arabs *dergmuse*. The branches of this plant are used in tanning, and to it, according to Mr. Jackson ('Edinburgh Medical and Surgical Journal,' vi. p. 457), the morocco-leather owes its peculiarities. By the most recent chemical analyses, euphorbium seems to consist of resin, wax, and saline matter (mostly malates). The resin is the active principle, and differs in some respects from most other resins, particularly in its less solubility in alkalies.

Euphorbium is a powerfully acrid substance, causing irritation and inflammation of the parts with which it comes in contact, and by sympathy affecting the nervous system. The dust received into the nostrils or eyes occasions violent sneezing and lachrymation, or even more serious affections of the eyes, so that it is necessary for those who grind this drug to protect the face by masks. Delirium and stupor approaching to apoplexy have followed the inhalations of the dust. When swallowed, it causes, in small doses, vomiting and purging; in larger doses it produces inflammation of the stomach, and sometimes proves fatal. It is now little used, even as an external application to produce vesication or ulceration, except by veterinary surgeons, and even by them cautiously. It is sometimes used as an errhine, largely diluted with starch, and enters into the composition of some cephalic and eye-snuffs; but it is apt to be violent in its effects. In case of poisoning by it, demulcent or oily fluids should be given, and venesection employed if much inflammation ensue.

EUPION, a liquid obtained by Reschenbach from vegetable tar, especially that from beech-wood. The process for procuring it is operose and complicated. Its properties are—that it is very limpid, colourless, inodorous, and tasteless; it boils at about 117° Fahr., and distils unchanged; it remains fluid at 4°. It is insoluble in water, but dissolves in alcohol, oil of almonds and of olives, oil of turpentine, naphtha, &c.; it dissolves chlorine and bromine; which are evolved when it is heated, and it also takes up camphor, stearin, and naphthalin, at common temperatures, but when heated, in larger quantity; with iodine it forms a blue solution. It dissolves phosphorus, sulphur, and selenium when heated, but the greater portion is deposited on cooling. Caoutchouc swells in it, and when heated dissolves. It is not altered either by exposure to air or by acids or alkalies. It probably consists chiefly of hydride of amyl, or a mixture of the hydrides of the ethylic series of radicals.

EUXANTHIC ACID ($C_{42}H_{17}O_{21},HO$). *Purreic Acid.* There is a yellow or brownish matter met with in commerce under the name of *purrée*, or *Indian yellow.* It is imported into Europe from the East Indies, but its origin is involved in obscurity; by some it is supposed to be a deposit which forms in the urine of the camel, the elephant, or the buffalo; by others it is believed to be an intestinal concretion of some animal. This material, whatever its origin, consists principally of the magnesia salt of a peculiar acid, to which the above name has been given. This acid is extracted by washing the Indian yellow with boiling water, and then dissolving it in boiling dilute hydrochloric acid. On cooling, this solution deposits pale yellow crystals of euxanthic acid.

Euxanthic acid is very slightly soluble in boiling water, but very soluble in boiling alcohol. Cautiously heated in a narrow tube, euxanthic acid decomposes and forms a yellow sublimate, consisting of *euxanthone, or purrenone* :—

$$\underbrace{C_{42}H_{18}O_{22}}_{\text{Euxanthic acid.}} = \underbrace{C_{40}H_{12}O_{12}}_{\text{Euxanthone.}} + 2CO_2 + 6HO$$

With the exception of the salts of the alkalies, the euxanthates are mostly insoluble in water.

Treated with chlorine, bromine, nitric acid, or sulphuric acid, it yields substitution products, of which the following are the names and formulæ of the principal :—

Bichloreuxanthic acid . . .	$C_{42}H_{16}Cl_2O_{22}$
Bibromeuxanthic acid . . .	$C_{42}H_{16}Br_2O_{22}$
Nitreuxanthic acid	$C_{42}H_{17}(NO_4)O_{22}$
Hamathionic acid	$C_{26}H_{14}O_{24}S_2O_6$?

Euxanthone yields similar substitution products :—

Trichloreuxanthone . . .	$C_{40}H_9Cl_3O_{12}$
Tribromeuxanthone	$C_{40}H_9Br_3O_{12}$
Porphyric acid	$C_{20}H_4(NO_4)_2O_6$?
Oxyporphyric acid	Unknown.

EUXANTHONE. [EUXANTHIC ACID.]

EVANGELIST is the Greek appellation *Euangelistes* (εὐαγγελιστής, from εὐ and ἄγγελος), which signified a messenger of any good news, as in Isaiah xli. 27, of the Septuagint version. In the first ages of Christianity it was a general name of all those who, either by preaching or writing, announced the "glad tidings" of the Christian revelation. The learned Hooker, in his 'Ecclesiastical Polity,' b. v. § 78, says that "Evangelists were presbyters whom the Apostles sent forth and used as agents in ecclesiastical affairs." They were similar to the class of ministers who in modern times are known as itinerant preachers. The deacon (subordinate minister) Philip is called an evangelist (Acts xxi. 8; see Grotius on the passage); so Ananias, Apollos, Timothy, and several others. St. Paul, in his epistle to the Ephesians (iv. 11), places evangelists in the third rank of ecclesiastical officers; thus, apostles, prophets, evangelists, pastors, teachers. Mosheim says the name was applied to all those, in the infancy of the Church, who had received the gift of tongues. The use of the term is now confined to the four writers to whom the canonical gospels are attributed,—Matthew, Mark, Luke, and John,—and the gospels themselves are not unfrequently, though incorrectly, called the Evangelists. St. Jerome states that the symbols of the four evangelists are a man, a lion, a calf, and an ox; but St. Augustine declares them to be a lion, a man, an ox, and an eagle. (Ezekiel, i. 5–10; Rev. iv. 7.) Dr. Campbell, in his 'Dissertation on the Gospels' (vol. i., p. 126, &c.), gives a variety of learned and critical remarks on the word εὐαγγελίζειν, as the translation of the Hebrew בשר, *bashar*, 'læta annunciare,' 'to announce good tidings.' (See the word in Rose's ed. of Parkhurst's 'Gk. Lex. of the N. T.')

EVAPORATION is the transformation of liquid, and in some cases of solid substances into a gaseous state by the action of heat. According to circumstances the effect may take place slowly and without any apparent movement of the surface of the liquid from which the vapour rises, or it may take place rapidly, and be accompanied by an ebullition. In the latter case, however, the process is termed *vaporisation.* [BOILING OF FLUIDS; EBULLITION]. In the process of evaporation, electricity has some share, as will be noticed further on.

If a liquid be placed in an open vessel, it will be found gradually to diminish in quantity by a sensible or insensible evaporation, and it will at length disappear: the quantity of vapour proceeding from the same liquid in a given time is evidently proportional to the area of the exposed surface; but, with equal temperatures, the escape of vapour from different liquids will be found to take place with different degrees of rapidity. An evaporation of the waters at the surface of the earth is going on at all times, and over the surface of an ocean the aqueous vapour held in the atmosphere amounts to an enormous quantity: much of this vapour is precipitated to the earth in the form of dew, rain, &c., but it is probable that the atmosphere, at any place, is never entirely free from it.

The whole quantity of vapour which rises from a liquid having a given surface appears to depend upon the temperature of the liquid; but, in a given time and in the open air, it is influenced by the state of the atmosphere with respect to dryness or moisture: in dry weather, even in winter time, the evaporation is more considerable than in damp weather, but it is greatest when the atmosphere is both dry and warm. At equal temperatures, in a close vessel, the evaporation is the same whether the vessel containing the liquid contain also air or have the air exhausted from it; but in the latter case the quantity of vapour which a given degree of heat is capable of raising occupies the upper part of the vessel immediately, whereas in the former a certain time elapses before that quantity is disengaged.

In order to obtain a knowledge of the quantity of water evaporated in the open air, in a given time, the atmosphere being calm, Dr. Dalton suspended some in a cylindrical vessel of tin from one end of the beam of a balance, and raised it successively to different degrees of temperature by heat: he weighed the water before and after each experiment, during the continuance of which the temperature was constant; and the difference divided by the number of minutes gave, for that temperature, the weight of the water evaporated in one minute from the exposed surface. At the boiling-point (212° Fahr.) the evaporation of water from one square inch of surface was found to be equal to 4·244 grains per minute, and at a temperature expressed by 138° one grain per minute: between these limits the quantities of the evaporation, per square inch, in grains, are nearly proportional to the heights, in inches, of the columns of mercury, whose weights are equivalent to the elastic forces of the vapour at the different temperatures.

In these experiments no allowance was made for the effects depending on vapour previously existing in the atmosphere, these effects being very small compared with the elastic force of the vapour rising from the water at such temperatures. But Dr. Dalton, taking f to represent the elastic force of vapour in the atmosphere when at the point of saturation, and f' to be the elastic force of the vapour in the actual state of the atmosphere, the temperature of the air in both cases being that which is indicated by the thermometer at the time of the experiment, found that the quantity of evaporation from a square inch of surface, at such temperature, was proportional to $f-f'$, and might be expressed by $\frac{4\cdot244}{30}(f-f')$. ('Manchester Memoirs,' vol. 5.) The evaporation from ice has been determined by experiment both by Dalton and Gay-Lussac, and was found to be equal in quantity to that which, by computation, would take place from water at the same temperature.

To Dr. Dalton we owe also the discovery, admitting however that the aqueous vapour in the atmosphere has no influence on evaporation, that the quantity of vapour raised from a given surface of any liquid, at a given temperature, is directly proportional to the elastic force of the vapour at that temperature; therefore, if the elastic forces of the vapours from different liquids were correctly ascertained, a near approximation, at least, might be made to the amount of evaporation from those liquids. At a temperature equal to 212° (Fahr.) the elastic force of the vapour from water is equivalent to the weight of a column of mercury 30 inches high; the elastic force of the vapour of one kind of alcohol, to the weight of a column 68 inches high; and that of the vapour of one kind of ether, to the weight of a column 219 inches high.

It is stated by Mr. Faraday that, at temperatures above 60° or 80° Fahr., there is a small evaporation from mercury; at lower temperatures he could detect none; and he concludes that, below the temperatures just mentioned, the gravity of the particles of mercurial vapour exceeds their elastic force. In this material, as well as in all liquids which boil at high temperatures, the elastic force of the vapour is very small. Sulphuric acid, for example, boils at 640° Fahr., but it emits no vapour at ordinary temperatures. Most solid substances have vapours of such low elasticities, that the highest natural temperature cannot convert them into vapour: and hence Mr. Faraday concludes that the atmosphere does not contain any vapours of earthy or metallic substances. Camphor evaporates readily at ordinary temperatures, and deposits crystals on that side of the glass vessel which contains it which is nearest to the light. When ice is introduced into the Torricellian vacuum it immediately depresses the mercurial column upwards of $\frac{18}{100}$ths of an inch. This is at 32°, but even at zero the tension of the vapour of ice amounts to $\frac{1}{100}$ths inch: it is in consequence of this evaporation that drifts of snow and patches of ice disappear even during the continuance of severe frost.

A few cases occur in which a body passing from a liquid to a solid form acquires thereby an increase of temperature, and the most remarkable case is afforded in the freezing of water. While still existing in a liquid state, water has had its temperature reduced so low, that a Fahrenheit's thermometer in it indicated no more than 5°; but on being made to crystallise, by agitation or otherwise, so much caloric was immediately evolved, that the thermometer rose to 32°. But when, by evaporation, a liquid is transformed into a vapour, heat is abstracted, and a thermometer in the liquid indicates a depression of temperature, or the liquid becomes cooled. In some parts of India, ice is produced by exposing water during the night in flat unglazed earthen vessels resting upon any imperfectly conducting substances, as sugar-canes, dry stems of maize, and the like. The dryness of the air allows a considerable evaporation to take place, and a thin film of ice is produced. Similar processes are employed in other countries for the purpose of reducing the temperature of liquids. [Cooler.] To a similar cause must be referred the icy caverns of the Jura, of Connecticut, and of Illetzkaya in the steppes of the Kirghis; namely, the powerful evaporation of moisture caused by the vicinity of the warm and dry external air.

The pressure of the atmosphere on the surface of a liquid may retard but does not prevent the evaporation from taking place. Vapours, like gases, mix with other aëriform fluids according to their own laws, and as if they were diffused through a vacuum. Each atmosphere of vapour in the compound atmosphere acts on its own particles alone; so that the aqueous vapour in the atmosphere acts by pressure only on itself. The time that is occupied before a given space is saturated with a vapour varies inversely with the pressure; and with different vapours, under the same pressures, the time varies with the diffusiveness of the vapour. [Diffusion.] The conversion of a liquid into a vapour is facilitated by placing the vessel containing the liquid under the receiver of an air-pump and extracting the air: but the vapour itself acts by its elastic force on the surface of the liquid, and impedes, at least for a time, the escape of more than a certain quantity. Daniell found that when water was evaporated under the receiver of an air-pump in the presence of sulphuric acid, the rate of evaporation was inversely as the pressure. Consequently the cooling process may be greatly accelerated by employing some means of absorbing the vapour as fast as it is formed, thus allowing the evaporation to go on without impediment. The means of accomplishing this end were discovered by Sir John Leslie, who placed a shallow open vessel containing sulphuric acid or muriate of lime along with the vessel containing the water from which an evaporation was to take place under the receiver of the air-pump; when the vapour was absorbed as it rose, and the water was speedily converted into ice. [Freezing Apparatus; Cryophorus.]

If a glass bottle containing water be covered with a cloth which is kept constantly wet by the application of water, the evaporation from the wet cloth will soon diminish the temperature of the water which is in the bottle. A similar effect is produced, but in a higher degree, on moistening the bottle with some spirit, as alcohol; and if a cloth dipped in alcohol be applied to the ball of a thermometer, the mercury in the tube will descend while the evaporation continues: the cooling is found to be so much greater as the spirit is more volatile; and it appears to be the greatest when ether is employed.

The degree of cold thus produced is increased by any means which will accelerate the evaporation: thus, by wrapping a piece of linen dipped in ether round the ball of a mercurial thermometer, and exposing the apparatus to a current of air, the mercury in the tube has been made to fall as much as 45°. Dr. Cullen ('Essays, Physical and Literary'), of Edinburgh put a small quantity of water into a thin glass tube which was suspended in a vessel containing ether; and then, on placing the apparatus under the receiver of an air-pump and rapidly exhausting the air, the evaporation of the ether caused such a diminution of heat in the water that it was converted into ice. By a similar process, using sulphuret of carbon instead of ether, Dr. Marcet ('Phil. Trans.,' 1813) succeeded in freezing mercury. Still more remarkable cases are given under Ebullition.

For the method of ascertaining the amount of moisture in the air under any given temperature, see Hygrometer. The supposed connection between evaporation and electricity is noticed under Electricity, Atmospheric; and the importance of evaporation as a meteorological agent will be further considered under Rain; Meteorology, &c.; but we may here refer to the old opinion advocated by the Abbé Nollet and others, that "electricity increases the natural evaporation of fluids," and that it is more efficient in this respect when the vessels which contain them are conductors. Mr. Rowell ('Cause of Rain,' Oxford, 1859) suspended by means of silk threads, in a warm room over an oven in daily use, two shallow vessels each containing 8 ozs. of water. From one of the vessels was hung a small copper wire passing from the water to the earth. In the course of twenty-five hours the insulated vessel lost 2 ozs. 11 dwts. 15 grs., and the other vessel 3ozs. 6 dwts, thus showing an excess of evaporation from the non-insulated vessel of 14 dwts. 9 grs. A similar result was obtained when the vessels were exposed to the sun.

EVECTION. [Lunar Theory.]

EVERITT'S SALT. [Cyanogen, *diluted hydrocyanic acid.*]

EVERNESIC ACID. Synonymous with Everninic Acid.

EVERNIC ACID ($C_{34}H_{16}O_{14}$?), a crystalline acid, homologous with lecanoric acid, extracted from a species of lichen, the *Evernia prunastri*. [Lichens, Colouring Matters of.]

EVERNINIC ACID. [Lichens, Colouring Matters of.]

EVIDENCE (Judicial) denotes, in jurisprudence, the proper means of evincing the true state of facts which have become the object of judicial investigation; and the just use of such means for that end in these investigations is the proper object of those established rules which are received in the courts of justice as the law of evidence. This law originates in the practice of the tribunals, continues into the latest times for the most part still unwritten, and long retains the character of the age which conceived and formed it for immediate service. Gradually the course of ages, changing the manners and continually adding to the moral and intellectual wealth of the nation, brings with it the necessity at length of departing somewhat from the tradition of the fathers. Reforms are introduced by positive enactment, and other reforms succeed as confidence increases with experience of the improvement effected thereby in the administration of justice. In this way our statute-book comes to exhibit at distant intervals the traces of change, which might be studied with advantage, relative to the history and character of the nation, but from which little information could be derived respecting the principles and rules that constitute this branch of English jurisprudence. The great bulk of these remain at this day, as they have been for ages, the subject of tradition, the common law of the courts, the familiar rules of daily practice in the administration of justice. But we are apt to forget this when we turn to Justinian's 'Digest,' and point with something like contempt to one short chapter which appears there, as though it necessarily comprised all that was known to the Roman law on the subject of evidence. This is probably an error of the same kind with his who should assume that in the fragmentary provisions of our statute-book he finds the whole of the English law upon the same subject; but the wrong would be so much greater, as it is done to the memory of a people whose jurisprudence has been the light of modern nations and the cherished wealth of the greatest minds, and which for its wisdom and rectitude still secures them the position and authority of the masters of the world.

Judicial evidence, considered with regard to its sources, is derivable from living witnesses, and from written instruments; and viewed with respect to its production in court, and admissibility as the means of judicial inquiry, it is subject to conditions which in the order of things demand our earliest attention.

The first great condition of the admissibility of living testimony in this country is that it must be given under the sanction of an oath. It suffices, however, that it be such an oath as is binding on the conscience of the witness. No exclusive ceremony or form of words is prescribed by our law, and no further inquiry into the faith of the witness is permitted than is necessary to ascertain whether he acknowledges the existence and moral government of the Divine Being, and that he will punish falsehood and perjury, either in this life or that which is to come. Even that inquiry is not volunteered by the judge, though it is permitted to be made by the adverse party; for it is a presumption of law that every person, in this country, of sufficient mental capacity, entertains this faith, and the usual form of oath is tendered without preliminary question. But obvious incapacity of mind, whether it be the immaturity of young children or the defect of the insane, rebuts this presumption of the law, and imposes on the court the duty of making previous inquiry into the state of the witness's knowledge with regard to the nature of an oath.

The exemption, at an early period, from this necessity, of certain religious sects who entertain conscientious objections to oaths of any description, has recently been extended to all persons who allege conscientious motives for their refusal or reluctance to take the oath. This is a modification, still in the spirit of the general rule, rather than any exception to it, made in favour of tender consciences which are hindered from following the common practice by a scrupulous and reverent obedience to what they regard as the Divine Will.

Scarcely more an exception than this is the admission in evidence upon trials for homicide of the dying declaration of the injured person, who in that condition makes a statement unsworn of the circumstances under which he received his injury. These statements, says Lord Chief Baron Eyre, "are declarations made in extremity when the party is at the point of death, and when every hope of this world is gone; when every motive to falsehood is silenced, and the mind is induced by the most powerful considerations to speak the truth; a situation so solemn and so awful is considered by the law as creating an obligation equal to that which is imposed by a positive oath in a court of justice."

The production of written instruments as evidence upon a judicial inquiry must be accompanied with proof of due execution under the hand or seal, or hand and seal, of the parties thereto; and such proof ought properly to be by the attesting witness, if the witness be alive and can be found, and if it be in obedience to the law that such attestation appears to the instrument.

The effect of this general condition had been superseded by the early practice of the courts in respect of the seals of certain public offices and well-known officers, of which the judges took judicial notice, dispensing with the evidence required in other cases; and this with so much convenience to the suitors, and saving of needless expense, and without any experience therefrom of counterbalancing disadvantages, that the legislature, by the Documentary Evidence Act (8 & 9 Vict. c. 113), made all documents of any public company, which are evidence by force of any statute, admissible in evidence, if they purport to be sealed or impressed with a stamp, or sealed and signed, or signed alone, or impressed with a stamp and signed, as the particular statute may require, without further proof of execution. The same statute extends this favourable exception to other classes of seals and signatures, and it has been followed to the same purpose by subsequent statutes, particularly the General Evidence Act (14 & 15 Vict. c. 99), and the Chancery Practice Amendment Statute, of the same year (14 & 15 Vict. c. 86).

The brevity of human life has imposed on the courts the necessity of making another exception to this general condition in favour of ancient writings, which are admitted in evidence without proof of execution after thirty years from the date thereof, provided they appear, upon testimony, to have been produced from the custody in which it is reasonable to expect, if genuine, that they would be found.

Besides these general conditions of the admissibility of living testimony and written evidence, certain other exclusive limitations thereto, which have exercised a powerful influence on the administration of justice, still require to be noticed. Living testimony was liable, till within a very recent period, to be shut out on the ground of the *incompetency*, as it was called, of the person to give evidence. A person might be incompetent because he was interested in the matter in question, or in the event of the trial, or because he had been convicted of an infamous crime. These grounds of exclusion, abounding with injustice, and scarcely possessing a single recommendation, have at length been abolished. The immediate parties to the suit or action are consequently admissible witnesses in any proceedings, except proceedings in consequence of adultery, or for breach of promise of marriage, or the defendant in criminal proceedings. A husband and wife, so constantly regarded at common law as one person, are now competent and compellable to give evidence, although it be for or against each other, in any proceeding, except a criminal proceeding when one of them is defendant, or a proceeding instituted in consequence of adultery. Neither of them, however, is compellable to disclose any communication made to the one by the other during the marriage; and generally no person is compellable to answer any question if the answer to it would have the effect of criminating the witness, or the husband, or wife of the witness, respectively.

Available evidence, in the nature of written documents, is often excluded by the immediate operation of the revenue laws, when the parties have neglected to use the stamp appropriate to the instrument produced. This is now so far modified in many cases as to enable the parties to give the instrument in evidence on payment in court of the stamp-duty and a fine, provided it is not one of those instruments (such as bills of exchange) which the law does not permit to be subsequently impressed with a stamp.

There is also a numerous class of facts of which it is the policy of our law to exclude all evidence except it be of one description. Some facts, for instance, are proveable only by the record of a court of record; others by writing under the seal of the parties; others by writing under the hand of the parties, in the presence of attesting witnesses; and others, again, by writing under the hand of the parties merely. Of such facts, if the proper evidence required by law, duly drawn up and executed, has ever at any time existed, we shall see that in virtue of another rule of evidence, proof of a secondary order is admissible upon showing the loss or destruction of the original instrument. But if no such original evidence ever has been in existence, the facts themselves, although their existence may be otherwise credibly attested, are not proveable in a court of law.

Evidence, again, which would be of the most cogent effect if it were accepted, is often so tainted in its origin, that it is not merely worthless, but absolutely inadmissible. Instruments which in their contents are most relevant to the inquiry, and have been to all appearance duly executed by the parties, may have been forged, or executed under duress, or in such a condition of mental incapacity that the person circumvented could not be held to be *compos mentis*. Again, a confession of guilt is popularly regarded as superseding the necessity for further inquiry; and this is not a modern opinion merely. *Reum confitentem habete*—used to resound in the Roman Forum as conclusive to the minds of the *judices*. The most experienced of our English judges, however, have learned to regard such evidence with anxiety and distrust; and, accordingly, when the confession is obtained under a promise or a threat by one who seemed to possess the power of giving his words effect, our law, with a commendable tenderness for human infirmity under circumstances so painful, rejects the evidence as too tainted in its origin to be deserving of credit, and too dangerous to innocence to allow of its being submitted to a jury. When the confession is perfectly voluntary it is admissible, but only as against the person who made it. As against all others it is worthless,—the law entertaining a jealous dread of the feeling of revenge in a malignant mind, and the cruel devices to which that passion has recourse for gratification. But this does not prevent an accomplice being made a witness, although he necessarily thereby criminates himself; for his evidence is no longer confession merely, but evidence given upon oath, and subject to cross examination by the adverse parties. Again, of that description of evidence called *hearsay*, which is admissible on certain questions of a public and *quasi* public nature, only that is admissible which can be shown to have originated *ante litem motam*; for it is obvious that, after the question at issue definitely emerges into public view between opposing interests, even people who are not directly concerned themselves, or in any way tampered with by the parties who are, yet are so liable to be moved by considerations that bias the mind and colour the testimony, that their sayings, although the authors are since dead, uttered under such influences, unsworn, and subject to no cross-examination, are excluded as mere sources of error and destitute of credit.

This is a compendious view of the operation and grounds of the general conditions upon which the admissibility of evidence by the law of this country depends. Those general rules descriptive of the evidence itself, and demonstrative, among all that is admissible, of that only which ought to be produced, come now to be stated with similar conciseness.

The first of these rules requires that the evidence should be relevant to the points actually in issue between the contending parties. To ascertain and exhibit these points is the principal office of the record. The sole purpose of what is technically termed pleading, is to reduce the dispute between the litigants to one or more definite and simple propositions, affirmed on the one hand and denied on the other, concerning the same subject, and in the same respect. The parties are then said to be at issue. One of the greatest of those evils which had crept into the system of pleading, and corrupted it from its original intention, had gone far, by means of what is called the general issue, to frustrate the chief purpose of the record as the authentic account of the precise matters in difference, and the determinate rule of the Nisi Prius evidence. The general issue, a quarter of a century ago, was a denial of the statement of the cause of action, so indefinite as to give the defendant the choice of several courses at the trial, and the plaintiff no notice what defence he was to meet, until the instant that he was called on to produce rebutting evidence. Together with the loss, in this way, of the substantive benefit of pleading, there was also such an increase of attention to matters of mere form, that it had become a refined subtlety and an elaborate snare. The great object of the new rules of pleading was to secure definiteness and simplicity, and singleness in the issues on the record; and since the publication of these rules, although the general issue still remains in name, and perhaps in form, yet, with the exception of some cases reserved by statute, it is now so defined and restrained by these same rules, that relevancy in the evidence is with much reason required, and always with great propriety very strictly enforced.

It is impossible here to omit all mention of a rule which writers upon evidence discuss at great length in their treatises, as though it formed an integral part of their subject. This rule requires that the evidence produced at the trial should correspond with the allegations placed on the record. It is plain to common sense that this is a rule of great importance to the suitor. It is clear that a person who alleges one thing on the record and produces something very different in evidence at the trial, cannot hope to succeed with either, unless there be an amendment somewhere to reconcile the difference. But then it is clear also that the proper evidence in the case never can admit of any tampering, paring, and altering; and as the allegations on the record may well be amended to meet the state of facts proved at the trial, it seems to follow that this is a rule of pleading rather than of evidence.

The evidence relevant to the issues admits of a distinction into primary and secondary; and this distinction forms the basis of another general rule, which requires the suitor to produce the best evidence of which the subject is susceptible. We have already seen that the law, for reasons not necessary here to be considered, requires some transactions to be reduced into writing and signed, others into writing under hand and attested by witnesses, and others into writing under seal; and where writing is not required, but the parties of their own accord have given this permanent form to their meaning and intentions, the law accepts this as the more certain and therefore better evidence of the transaction. In these several instances, the original writing forms what is termed in the rule the *best* evidence of the transaction which constitutes the contents of the document; and if suitors might at will produce it, or offer other evidence of its contents, whether oral or written, a ready opportunity of fraud would exist which the suitor at a push might be in great temptation to use. While the original writing exists, therefore, it is the only admissible evidence of its contents, unless it be withheld by the other party to the action. In that case, or in case it be lost or destroyed, secondary evidence is then receivable; and, as there are no degrees of superiority in secondary evidence, this may be either oral or written.

A numerous list of exceptions to this rule has been created by statutory provision, making examined or certified copies of various public documents, registers, and legal proceedings, evidence of the contents of the originals; and so much has public convenience been consulted by this exception, that parliament consented to the insertion of a general provision in the Evidence Act (14 & 15 Vict. c. 99), greatly extending the range of this privilege.

It is often laid down as a distinct rule in the law of evidence that parol testimony is not admissible to contradict, vary, add to, or subtract from the terms of a valid written instrument. This, if not a branch of the rule in respect of best evidence, certainly follows that other with the necessary sequence of a corollary, and is its proper complement.

Upon this rule also the imperfection attending human transactions has forced several exceptions. It is clear that instruments containing technical words used technically, or common general words used in a peculiar and local sense, and contracts so drawn up as to leave unexpressed, but intentionally implied, the usages of a particular trade, or the customs of an ascertained locality, would be misconstrued, if construed at all, without parole evidence of such use, usages, and customs. But if the effect of such parole evidence when given be inconsistent with the terms of the writing, the new matter will be rejected by the court, as being expressly excluded by the document, and this will be construed without extraneous assistance, as containing the full expression of the intention of the parties. Evidence of any subsequent agreement of the parties is only admissible to contradict or vary a written instrument when it is in a form of equal solemnity with that which is required by the law in respect of the instrument to be varied or contradicted. Parole contradictions, or additions to any written instrument whatever, are altogether inadmissible when contemporaneous with it. But this rule does not shelter fraud or illegality, so as to debar from proving it by oral testimony; it does not exclude verbal evidence of mistake when relief therefrom is sought in equity; it does not shut out proof of the want of consideration for bills of exchange, because that is only a presumption of law in their favour, and is not expressed in the writing.

It is a rule of evidence that *hearsay* is inadmissible as evidence on matters of private interest between party and party. By the rule requiring testimony to be given under oath, such evidence as this would be excluded, but not by this rule only. The uncertainty, first, of what was said or done; secondly, of what was meant thereby; and thirdly, whether the full meaning and entire truth were conveyed by the words or acts, or both acts and words spoken to, must be a sufficient ground for excluding this kind of evidence. Yet here too we are obliged to take notice of a number of exceptions.

In cases of homicide, and these only, although greater scope was given to it in earlier times, exception, we have seen, is now made in favour of the dying declaration of the injured person, when the circumstances of the injury are the subject of the statement. The apprehension of death, followed afterwards by that event, is an indispensable condition of the admissibility of the declaration, as forming an equivalent to the sanction of an oath. And considering that the events are likely to be recent, and the impressions of them painfully emphatic, whilst the words of the statement are naturally presumed to be sobered down to the truth by the solemn apprehensions of approaching dissolution, it is not unreasonable to believe that such a declaration satisfies the adjuration addressed to all witnesses, and states the truth, the whole truth, and nothing but the truth, touching the matter in question. But if the declaration be such, that it appears to be incomplete, and that a modification was intended but not expressed, it will not be received in evidence.

Another exception to the rule is made in favour of entries in books against the pecuniary or proprietary interests of the person who made them, and is since dead. It was contrary to his interest to have made them at the time, and it is essential to this admissibility that death should have previously removed him from all possibility of personal interest in the use of them as evidence. There is this, however, which is remarkable about the effect of such entries, that they are admitted as evidence, not only of the fact which forms the main purpose of their existence, for instance that a pecuniary claim has been satisfied, but of what is incidental thereto, for instance of the facts on which the claim itself was grounded.

Entries made in the course of business or the routine of office, when they are contemporaneous with the events which they record, and the person who made them is since dead, form another exception to the general rule excluding hearsay as evidence. But these entries, unlike those already referred to, are evidence only of that which it was the business of the person making them, to record, and more. The routine of business, the absence of sinister motives, the cognisance which others have of the same facts and entries operating on such a person as a check, and the powerful interest which he usually has in being correct, form together no weak argument for the admissibility of such evidence. The effect of it when admitted will be indefinitely varied by the existence or absence of corroborating circumstances.

Another general exception to this rule admits *hearsay* as evidence on questions of public and quasi public interest. In this general description we include such matters as a claim of a public highway, right of common *pur cause* of vicinage, manorial customs, and questions of pedigree, which when once involved in doubt, either from the absence of written documents, or the ambiguity of their contents when they exist, are scarcely susceptible of any other description of evidence. Even in these cases, however, the evidence admissible is not hearsay indiscriminately originated in any quarter, or at any period of time. We have already ascertained the limit placed upon it in respect of time. And in respect of source, it is only those, whose interest in the claim or right engaged them to inquire, and gave them opportunity of knowledge on the subject, that are recognised as competent to be authors of this kind of tradition which the courts are obliged to receive in such cases. The effect of that rule is to define the circle, from which hearsay is derivable, by the range of legal interest possessed in the matter in question, so that in pedigree cases, for instance, the tradition of blood-relations only is receivable in evidence. This kind of interest which is thus recognised by the law as the condition on which depends the admissibility of hearsay, would entirely derogate from the worth of the evidence when admitted, if that other rule which has been referred to did not exclude all hearsay originated at a period subsequent to that when the right or claim began to emerge as a matter in difference.

We have thus offered a compendious view of the chief principles and rules of the English law of evidence, and for further details and a full discussion of the subject we must refer to such writers as Taylor, Phillips, Greenleaf, Best, and Starkie.

EVIL EYE. It was an ancient superstition that certain persons were endued with the power of injuring those on whom they cast a hostile or envious look. The eyes of such persons were supposed to dart noxious rays on every object on which they were fixed. This power of injuring with the eye was called *Bascania* (Βασκανία) by the Greeks, and *Fascinatio* by the Romans. Plutarch 'Symposiacs,' lib. v. quest. 7, states, on the authority of Philaretus, that the Thybiens who inhabited Pontus were deadly, not only to babes, but to men grown, and that whomsoever their eye, speech, or breath, would reach, were sure to fall sick and pine away. Several writers who have collected the testimonies of the ancients concerning it (as Potter, 'Archæologia Græca,' lib. ii. c. 18, and Alsarius, 'De Fascino,' in 'Grævii Antiq. Rom.,' tom. xii. p. 885), may be consulted for particulars. Those who enjoyed great prosperity, or met with any extraordinary good fortune, and such as were too much elated by praise and flattery, were more particularly liable to the effects of fascination. Hence when the Romans praised any thing or person, they used to add, *Præfiscini* or *Præfiscine dixerim*, to avert any fascination that might ensue, and to prove that their praise was sincere.

It is remarkable that the same superstition prevails to the present day in several parts of the world: even in the northern part of our island, and in Ireland. In Greece it is at present called *kako mati* (κακο ματι), and its effects are averted by spitting, in the same manner as was practised by the ancients against fascination (Theocr., 'Idyl.' vi. 39) and ill omens of every kind. In Italy it is called *malocchio*, and among the lower orders of people its effects are supposed to be very powerful and fatal. When praise is bestowed on beauty, riches, or any other advantages, the person praised immediately exclaims, "se malocchio non vi fosse," from an apprehension that the praise may not be sincere, but proceeds solely from a malicious intention to injure. This exclamation is accompanied with a sign of the hand, or by holding up pieces of coral, shells, or various kinds of stones worn as amulets.

The belief in fascination is extremely ancient, and in the opinion of some is connected with the story of Medusa and the Gorgons, whose eyes caused immediate destruction. From this source the superstition of the evil eye is probably derived.

Virgil alludes to this superstition in his third Eclogue:—

> "Nescio quis teneros oculus mihi fascinat agnos."

Scot, in his 'Discovery of Witchcraft,' has one or two passages relating to it. He says, p. 35, "The Irishmen affirm that not only their children but their cattle are (as they call it) *eye-bitten* when they fall suddenly sick." It is likewise mentioned in Martin's 'Description of the Western Islands of Scotland,' in Heron's 'Journey,' vol. ii. p. 228, and in several volumes of the 'Statistical Account of Scotland,' as still believed there.

"Nothing," says Dallaway, in his 'Account of Constantinople,' 4to. Lond. 1797, "can exceed the superstition of the Turks respecting the Evil Eye of an enemy or infidel. Passages from the Koran are painted on the outside of the houses, globes of glass are suspended from the ceilings, and a part of the superfluous caparison of their horses is designed to attract attention, and divert a sinister influence."

Lane, in his 'Modern Egyptians' (1836), testifies to the general belief in the ill-effects of the evil eye still prevailing in Egypt, and details the superstitious precautions taken to guard against it.

EVIL, KING'S. [SCROFULA.]

EVOLUTE. [INVOLUTE and EVOLUTE.]

EVOLUTION. [INVOLUTION and EVOLUTION.]

EVOLUTIONS. [MANŒUVRE.]

EVONYMINE. A crystalline, bitter, and neutral non-azotised substance, found in the *Evonymus europæus.*

EXAMINATION. [EVIDENCE.]

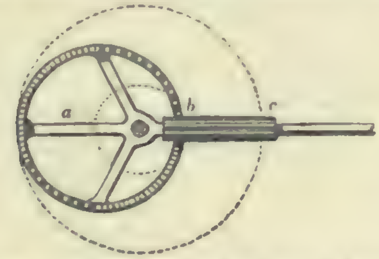
EXANTHEMATA (*Exanthematous diseases*), ἐξάνθημα, an *efflorescence;* a term under which are comprehended the eruptive fevers, or the diseases commonly termed rashes. Rashes are superficial red patches, variously figured, and diffused irregularly over the body, leaving interstices of a natural colour, and terminating in cuticular exfoliations. Fever is an essential element in the definition of an exanthematous disease, as this term is usually employed by nosologists; but the writers on cutaneous diseases give to it a modified signification, and comprehend under it only those diseases which are properly termed rashes, whether those rashes are attended with fever, and whether they are contagious or not. Thus Dr. Bateman comprehends under the order Exanthemata measles, scarlet fever, nettle-rash, roseola or the rose, purpura, and erythema.

EXARCH was the title of the governor of Italy under the Byzantine Emperors, established by Justinian after the reconquest of Italy from the Goths in the sixth century. The first exarch was Narses, who was also the greatest, about A.D. 568, and who held the exarchate for fifteen years. The residence of the exarch was at Ravenna, then a sea-port town, and the great entrepôt between Greece and Italy; and Italy was nearly equally divided between the kingdom of the Longobards and the exarchate of Ravenna, which included the Romagna, the Adriatic coast, Venice, and Naples; while the more inland portions were held by the Longobards. The exarchs, who were generally chosen among the officers and favourites of the Byzantine court, were of course removable at the pleasure of the Emperor, but several of them remained in their office to the end of their lives. Their administration was often marked by acts of oppression and treachery, the results of Byzantine corruption as well as of the peculiar difficulties of their situation. They were engaged in frequent hostilities against the Longobards who had invaded the greater part of Italy, and were also not unfrequently at variance with the popes, and their authority was often confined within the walls of Ravenna. At last, in the year 752, Ravenna being taken by Astulf or Astolphus, king of the Longobards, the exarchate, as well as all dominion of the Byzantines over North Italy, was at an end; but the Greek emperors still retained possession of parts of Apulia and Calabria, where Bari became the residence of the catapan or Byzantine governor. (See 'Chronological Series of the Exarchs,' in Petau, 'Rationarium Temporum.')

EXCENTRIC. [PTOLEMAIC SYSTEM.]

EXCENTRIC, or ECCENTRIC, in machinery, a kind of wheel, or revolving cam, in which the axis or centre of motion does not coincide with the geometrical centre, or in which the periphery is not circular. A general notice of such contrivances, and a representation of the kind of excentric employed for working the valves of a steam-engine, will be given under WHEELS.

Excentrics of various kinds form an important class of mechanical expedients for converting one kind of motion into another. They afford means for converting continuous circular motion, in various ways, into alternating or intermitting rectilinear motion, or into curvilinear, though not rotatory motion. They also furnish means for producing, from the uniform speed of one revolving shaft, rotatory motion of continually varying speed in shafts placed in connexion with it. As an illustration of such an application, Professor Willis, in his 'Principles of Mechanism,' refers to an excentric crown-wheel contrived by Huyghens to produce some of the complex movements of a planetarium. The subjoined diagram will illustrate the action of this apparatus, *a* representing the crown-wheel, which is mounted excentrically upon a shaft which revolves with a uniform speed, and *b c* a pinion driven by it, and made so long that it may be acted upon either by that portion of the periphery of the crown-wheel which is nearest to its axis, and which describes in its revolution a path indicated by the small dotted circle, coming in contact with the pinion at *b*, or by the opposite portion of the periphery, which describes the path indicated by the large dotted circle, and engages the pinion at *c*, where it is intersected by that circle. As the distance from the axis of the crown-wheel to the point *b* is little more than one-third of the distance from the axis to *c*, and as the velocity of the axis or shaft is uniform, it follows that the pinion will be driven nearly three times as fast when in contact with that part of the periphery of the crown-wheel which lies farthest from the axis as when in contact with the part which intersects it at *b*, while every intermediate portion of the periphery of the crown-wheel will impart a different, but intermediate velocity. Such a combination of wheels might be driven by the pinion, in which case, supposing the pinion to have a uniform velocity, that of the crown-wheel, or rather of its axis, will vary. Further variations might be introduced by making the periphery of the crown-wheel of other than a circular form.



Excentrics may be driven by bands or straps; but unless the bands be very highly elastic, it is necessary to apply a stretching pulley or roller, which may be pressed against the strap by the action of a weight, to maintain a uniform degree of tension.

EXCENTRIC WHEELS. [WHEELS.]

EXCENTRICITY, a term applied to the ratio which the distance between the centre and focus of an ellipse or hyperbola bears to the whole semiaxis. [ELLIPSE; HYPERBOLA.] With regard to this word, it should be noted that in the older writings on conic sections it was not the *ratio* of these two lines, but the former of them, namely, the distance between the centre and focus, which was called the eccentricity.

Let a be the semimajor axis of an ellipse or hyperbola, b the semiminor axis, and e the eccentricity; then

$$\text{in the ellipse } e^2 = 1 - \frac{b^2}{a^2}$$

$$\text{in the hyperbola } e^2 = 1 + \frac{b^2}{a^2}$$

EXCESS. For a peculiar mathematical use of this term, namely, the *spherical* excess, see SPHERICAL TRIANGLE.

EXCHANGE. The rules by which operations of exchange are conducted must be either the simple rule of three or the chain rule.

In the simple and direct operation nothing but the rule of three can be required. Thus, the exchange between London and Paris being 25 francs 55 centimes to the pound sterling, 6732 francs are converted into English money by finding the fourth term of the following:—

25·55 : 1 : : 6732 : the answer.

and 139*l.* 14*s.* 6*d.* can be converted into French money by

1 : 25·55 : : 139*l.* 14*s.* 6*d.* : the answer.

But in the case of the indirect operation of passing money from one country into another through a third, a double operation of the rule of three is requisite, which may be facilitated by the use of the chain rule. Suppose, for instance, that the exchange between London and Paris is 25·55 francs to the pound sterling, and that the exchange between Paris and Hamburg is 100 marks to 189 francs. Then, to find out the *arbitrated* value (as it is called) of 139*l.* 14*s.* 6*d.*, remitted to Hamburg through Paris, we have

100 marks are worth	189 francs
25·55 francs „	1 pound
139*l.* 14*s.* 6*d.* „	How many marks?

It is however more common, first to establish an arbitrated *rate* of exchange, by putting 1*l.* in the place of 139*l.* 14*s.* 6*d.*, and then deducing the value of the latter sum. This is more convenient, because it establishes a rate once for all until the exchanges vary.

But the student must not content himself with the simple exposition above given. There are many little matters of business which cannot be explained here, but which may be found in such works as Tate's 'Commercial Arithmetic,' and the 'Counting-House Guide' of the same author.

EXCHANGE. The term exchange is commonly employed by merchants to designate—first, the operation of the written instrument, by which the debts of persons residing in different countries, or in different parts of the same country, are brought to a condition for final liquidations; and, second, the varying price of such negociable instruments in the market, which price is determined by the course of mercantile transactions, by means of which the obligations of debtors residing at a distance from their creditors, are discharged without the transmission of coined money.

The first division of the subject is discussed under the title BILL OF EXCHANGE; the following article will comprise the second, and will include an investigation of the principles on which exchange transactions are based.

International, or, as it is commonly called, foreign trade, arises out of the unequal or exclusive capacity of different countries to produce the various objects of desire. One country, for instance, has abundance of coal and iron; another enjoys a climate especially adapted to the culture of the vine; whilst a third possesses some peculiar advantages for the growth of wheat. If interchange were not restricted by legislative enactments, if trade were perfectly free, the first country would supply the other two with iron wares, taking from the second wines, and from the third wheat; whilst the two last would, in like manner, exchange their respective productions with each other.

Peculiarities of soil and climate, abundance and cheapness of land or of labour, the exclusive presence of certain animals, vegetables, or minerals, high excellence in particular arts and manufactures, all give rise to interchange between nation and nation. Every country has some peculiarity which gives it an advantage, with respect to that peculiarity, over all other countries: it is by means of interchange that such advantages are shared equally among all.

In the article BILL OF EXCHANGE, already referred to, we have explained how this mode of settling accounts, between parties in different countries, arose; and the various legal rights, of the parties to a bill of exchange, are also in that article, fully explained.

In investigating that part of the subject which belongs to the present article it is necessary to bear in mind that different countries make use of different coins—different in denomination, in weight, and consequently in value. Thus, the pound is the money of England, the franc that of France, the dollar that of America. These several coins contain very different quantities of the precious metals. The dollar, for instance, contains about five times as much silver as the franc, whilst the guilder contains only twice as much. The value of a currency depends on the quantity of pure metal, contained in the coin which forms its legal tender, alloy being left wholly out of the account.

In the language made use of by merchants, the existence of a *par of exchange* is usually assumed. The Par of exchange, here in England, is the expression of the relative worth of the coins of two countries, with each other, at our Mint standard price. ('Report of House of Commons Committee of Secrecy on Bank, &c.,' 1819, p. 206.) Between two countries making use of the same metal a par may exist; but between two countries, one of which makes use, as its legal tender, of gold, and the other of silver, an invariable par cannot exist.

The following is a statement of the contents, in pure silver, of the several coins forming the money of account, of the several countries specified:—

	Grains.
Franc of France	69·4
Mark of Hamburg	105·15
Florin of Amsterdam	146·8
Dollar of America	370·1

Hence the mark is worth, in Paris, 1·515 francs; in Amsterdam, 14 stivers 5 pfennings; and in New York, 28·2 cents.

Gold is now a legal tender in America, and the sovereign is by law worth 4·87 dollars, making the eagle of 10 dollars worth 2*l.* 1*s.* 0¾*d.*; the dollar (of gold), 4*s.* 1¼*d.*; and the 100*l.* sterling equal to 487 dollars; all of which are different expressions for the *par* between England and the United States—both being gold-using countries.

We have said that a par of exchange cannot exist, between two countries, making use of different metals, as the standard of their respective currencies; we shall now explain the reason. Gold is the standard in England. The silver coin of England possesses a conventional value, independent of the market value, and the latter may fluctuate without affecting the former. Foreign coins, the franc or the guilder for instance, possess no such conventional value. They are merely a commodity, liable to fluctuation, with the varying price of silver.

Some time ago it was found that, in a period of ten years, the price of silver in the London market varied from 4*s.* 10½*d.* to 5*s.* 1*d.* per ounce of 444 grains pure, the medium price being 4*s.* 11⅓*d.* to 5*s.* The extreme prices gave the following results:—

Price of Silver per oz.	Value of Franc.	Value of £1.
s. *d.*	*d.*	f.
4 10½	9⅛	26·30
5 1	9·54	25·15

Thus making a fluctuation in the so-called par of exchange of rather more than 4½ per cent.

The assumption of a par of exchange, where no par can exist, is likely to lead, at times, to great inconvenience. Suppose, for instance, that the par between Paris and London be assumed at 25·58 f., which is about the medium. Suppose further that the exchange is quoted at 26·30 f.; what would be the inference? Why that exchange was 2·8 per cent. in favour of England, and (the cost of transmission being much less than the above difference) that consequently bullion was about to pour into London. But suppose that, at the same time, the market price of silver had declined, in London, to 4*s.* 10½*d.* per ounce, and gold, in Paris, had advanced in a like ratio, what would be the effect? Why the supposed premium, in favour of England, would vanish, and the par, for the time being, would be brought to coincide with the actual rate.

The mining countries are the only exceptions to the rule, that no country can have the exchange permanently favourable or unfavourable with the whole world. 'Senior's Lectures Lect. I. on Transmission of Precious Metals, p. 17.

Though there exists no invariable par of exchange it is extremely useful to the merchant to know the average value of the currency of every country with which he trades, in order to ascertain, what may be called the *approximate par*, which must be the pivot around which fluctuations will necessarily turn. This approximate par (a term which we make use of for the sake of conforming, as nearly as truth will permit, to the language familiar to merchants) should be grounded, on the average value of a currency, taken on a period sufficiently long to include fluctuations from highest to lowest. To the approximate par so taken will be the tendency of the rate of exchange to conform.

The approximate par of exchange will be liable to be affected by four pairs of circumstances, in addition to a rise and fall in the price of the precious metals. These are—

1. Changes made by the supreme authority in the quantity of the pure metal contained in the coin by way of increase or diminution.
2. Depreciation from the use of paper money, and restoration.
3. Clipping, and restoration.
4. Wear and tear, and restoration.

1. *Legal Changes in the Coinage.* Governments have not unfrequently found the diminution of the quantity of the metal, contained in the current coin, an easy way of getting rid of improvidently contracted debts. The English pound was once a troy pound of silver; it is now about four ounces. The French livre, once probably the same quantity, is now less than a *seventieth* part of a lb.

A government, having borrowed *so many pounds* of its subjects, would find it a very convenient thing, when the day of payment should come round, to call ten or fifteen shillings 'a pound;' and as it would have all the debtors in the kingdom on its side, popularity would be divided on the measure. But although creditors, at home, may be compelled to submit to this robbery, creditors abroad cannot. Their contract is to receive a given sum of the money of their own country, and the only effect, of any debasement, will be that the foreign debt will require more of the debased money to liquidate it; in other words, exchange will fall in the ratio of the debasement. Thus suppose the sovereign to be reduced in weight 10 per cent., exchange on the Parisian Bourse, if at 25·58f., would fall to 23f. 2c. If, on the other hand, the franc were reduced, exchange would rise.

We can illustrate this by two historical facts. Formerly the Spanish dollar contained as much silver as 4*s.* 6*d.* sterling, and consequently the average value of 100*l.* was 444 dollars 44 cents. The weight of the dollar however has been since reduced, and it now contains only as much silver as 4*s.* 2*d.* sterling, so that the average value of 100*l.* sterling is now 480 dollars; the difference being 8 per cent. The old language of quotation however has never been wholly abandoned by the American merchants. They still assume the old par, so that when exchange is quoted at 10 or 11 per cent. premium—a premium which, as we shall presently see, could not be maintained for an hour—it is in fact at 2 or 3 per cent. only (the remaining 8 per cent. being nominal); and when it is quoted at 6 or 7 per cent. premium, it is in fact at 1 or 2 discount. The other fact to which we allude is the adoption of a gold standard, in the United States, at a rate, compared with silver, to render the American currency practically debased.

Before the introduction of the Gold Bill the average value of 100*l.* sterling, as we have seen, was 480 dollars; by the new standard, the quantity of gold contained in 100*l.* is now coined into 487 dollars, being a difference of 1·45 or nearly 1½ per cent. Thus the par between England and America is now 487 d.=100*l.*, or adhering to the old (erroneously assumed) par, a nominal premium of 9·45 per cent.

2. *Paper Money.*—One of the evils to which paper money is liable is depreciation from excess. The market price of money, like that of every thing else, varies in the inverse ratio of its quantity. If it be scarce it will be dear; in other words, all other things will be cheap. If, on the other hand, money be in excess, it will be cheap; in other words, much of it will be given in exchange for other things. To say that prices are advancing, is equivalent to saying that money is getting cheaper and cheaper. The effect of issuing paper money in excess is, then, to make money, both metallic and paper, cheap. Being cheap, it becomes desirable to export it; but paper money is not available for this purpose, and hence metallic money is alone exported. Bullion in the uncoined state would, under such circumstances, advance in price, but the sovereign would be still a sovereign; hence there would exist a motive to convert coined money into bullion, or to export it. Bullion however would not be exported, except when it was really cheaper here than in other countries.

During the Bank restriction the depreciation reached 27·9 per cent. Gold was then worth 5*l.* 8*s.* per ounce, and silver 6*s.* 11*d.*, estimated in paper money. But at these nominally high prices the proportion between gold and silver was precisely the present average proportion, namely, 1 to 15·52; or, gold at 3*l.* 17*s.* 10½*d.*, and silver at 4*s.* 11⅞*d.* The Parisian par was then 18·43f. per 1*l.* sterling (instead of 25·58f.) so that although *coin* might be sent away as a cheaper mode of conversion than melting, bullion would not necessarily be an article of export, unless when exchange was really, and not merely nominally, against us.

We have seen that the present average value of the dollar is 4*s.* 2*d.*; when silver was at 6*s.* 11*d.* the value would be 5*s* 9¼*d.* in the depreciated English money. Hence a debt in London of 100*l.* could be discharged with 346 dollars 18 cents, whereas now it would require 480 dollars. The dollars remained unchanged, but 100*l.* of 1813 was worth only 72*l.* 2*s.* in gold.

As the par of 4*s.* 6*d.* was then, as now, retained, the depreciation was met by a heavy nominal discount of 27$\frac{9}{10}$ per cent. It is unnecessary to pursue these calculations to other countries; the same principles apply to all countries.

It is scarcely necessary to observe, that, in the process of restoration, the phenomena are reversed. A restoration of the English currency, for instance, would be similar, in its effects, to a depreciation of the currencies of all other countries.

3. *Clipping the Coin.* In some countries the practice of clipping the coin still continues, and it is likely to continue just so long as people

will take clipped coin. If people would take shillings clipped into polygons, they would be so clipped in less than twenty-four hours.

The effect of clipping, on the exchange, is precisely similar to the two cases we have already examined. If the silver coin of France were clipped, to the extent of one-tenth of its weight, exchange would be affected to that extent. Instead of requiring only 25·58f., to purchase 1*l.* sterling on the Parisian Bourse, it would require 28·14f. Restoration would be equivalent to clipping the coins of other countries.

Some of the continental states, in which clipped coin circulates, have adopted an expedient to keep up the character of their money of account. This expedient is to transact all their dealings, with other nations, in what they call *Banco*, which may be defined money *as it ought to be*, to distinguish it from the current or clipped money, which may be called *money as it is*. The merchants keep their bank accounts in *money as it ought to be*, paying in the clipped money, or *money as it is*. They are charged with the depreciation, which is known by the term *Agio*. This is purely an arrangement of convenience.

4. *Wear of Coin.*—The case of a worn coinage is precisely similar to that of a clipped coinage, except that the latter is sudden in its effects, the former gradual. Hence depreciation, from wear, is much more likely to deceive, than that which arises from clipping. Restoration, by means of a new issue, reverses all the effects.

We have now enumerated the principal circumstances affecting the value of a currency. Fluctuations in the rate of exchange, proceeding from an alteration of the value of the medium in which price is quoted, are purely *nominal*; and so they are usually designated. They are alterations, proceeding from the altered quantity of the article purchased, and are analogous to an alteration of the price of wheat, from an alteration in the capacity of the imperial quarter.

What is usually called the *real* exchange is the actual market-price, determined by the same law as the price of sugar, corn, or broad-cloth, namely, the existing proportion between supply and demand.

The demand for bills of exchange arises out of the necessity of paying for importations. The supply arises out of the practice of drawing for the amount of exportations. If the supply and demand be equal—if for every pound's worth of goods imported there be exactly a pound's worth of exported goods to be drawn for—there will be no real exchange; that is, the real exchange, however much the nominal exchange may alter, will be at par.

When, however, the importations are not precisely equal to the exportations, exchange can no longer remain at par. An excess of importation would cause exchange to advance against the importing country. Let us suppose a case. Let us suppose that an actual or anticipated advance in the price of wheat causes the transmission of extensive orders to the north of Europe. This would produce a sudden demand for bills of exchange—not perhaps to the extent of the orders, for in all probability goods adapted to the markets of the wheat-growing countries would be sent in part payment—but, at all events, to a considerable amount. There would accordingly be an advance in the rate of exchange, first on the wheat-shipping ports, and next on all other countries. Thus, England imports wheat from Danzig, and exchange on Danzig rises. But exchange on Amsterdam is at par, as it is also at Amsterdam on Danzig. Hence the wheat-importer would buy a bill on Amsterdam, and with the proceeds would there buy a bill on Danzig. But the buyer of exchange on Amsterdam cannot go into the market without causing an advance in the ate. In this way the advance becomes general.

The real exchange, however, is subject to a limit beyond which it cannot advance. A rise in the exchange will be limited by the aggregate amount of the following items: 1. The cost of obtaining the precious metals here. 2. The charges of transportation. 3. The profit of the lender for the use of his money: which two last expenses form the scale of the rise of the exchange abroad. (Report of Committee of Secrecy, &c., p. 181.)

But an advance in the rate of exchange, even up to this point, cannot long be maintained. The tendency in an advance in the rate is to check importation and stimulate exportation. Articles which would only just pay with exchange at par would pay a profit sufficient to induce exportation where the exporter could secure 1 or 2 per cent. more for his draft. Thus, by the stimulus to exportation, the supply of bills would be increased to meet the demand, and *pro tanto* to check the advancing rate of exchange. On the other hand, an imported article which was only just paying when exchange was at par would cease to pay when it should cost the importer 2 per cent. more to make his remittance. Thus, whilst the cost of exporting the precious metals is the immediate check upon an advancing rate of exchange, the effect of the real exchange in stimulating or checking importation or exportation, as the case may be, is to work its own remedy. This natural and inherent tendency is assisted by the operations of the dealers in bills. Thus, the bills drawn on Great Britain in Italy almost always exceed in amount those drawn by Great Britain on Italy. One part of the business of a bill merchant is to buy up the excess of bills drawn in Italy on London, to sell them in any country on the continent that happens to be indebted to us, and this prevents the *real* exchange between Italy and this country from ever falling very low. The real exchange is, in fact, continually gravitating towards par, though at times superior forces may overcome that perpetual tendency.

Most of the errors which prevail in relation to the subject of exchange arise out of confounding the real with the nominal exchange. For the purposes of general reasoning, it is well to know what is the average value of the currencies of the several nations with which we have commercial relations; but for practical purposes the actual par for the moment should be rigidly calculated. Unless this be done, the practical merchant will be liable to continual error. For farther information on the subject, the reader may consult Mill's 'Elements of Political Economy,' chap. iii. sec. 16; Ricardo's 'Principles,' chap. vii., 'On Foreign Trade;' article 'Exchange' in the 'Encyclopædia Britannica;' and Tooke's 'High and Low Prices,' passim.

EXCHANGE, BILL OF. [Bill of Exchange.]

EXCHEQUER BILLS form the principal part of the unfunded public debt of this country. These bills are issued under the authority of parliament for sums varying from 100*l.* to 1000*l.*, and bear interest. They were first issued in the reign of William III.; and although their amount has since varied greatly at different times, the convenience which they afford to individuals and their advantage to the public have been such as to cause their constant issue. Their convenience to individuals arises from the circumstance of their passing from hand to hand without the necessity of making a formal transfer, of their bearing interest, and of their not being subject to such violent fluctuations as sometimes occur in the prices of the funded debt. This comparative steadiness in value is caused by the option periodically given to the holders to be paid their amount at par, or to exchange them for new bills to which the same advantage is extended; besides this, when a certain limited period has elapsed from the date of their first issue, they may be paid to the government at par in discharge of duties and taxes. The amount of premium that may have been paid at the time of purchase is consequently all that the holder of an exchequer bill risks in return for the interest which accrues during the time that it remains in his possession. The advantage to the public consists in the lower rate of interest which they carry compared with the permanent or funded debt of the nation, to which, however, they must in this respect bear some certain proportion. When the price of the public funds is high, the interest upon exchequer bills will be low; and if, through any public or commercial derangement, the funds should fall in price so as to afford a much more profitable investment than exchequer bills, the rate of interest upon these must be raised in order to prevent their payment into the exchequer in discharge of duties, a thing which would embarrass the financial operations of government. When first issued in the reign of William III., the interest borne by exchequer bills was *5d.* per 100*l.* per diem, being at the rate of *7l. 12s. 1d.* per cent. per annum. During the greater part of the war from 1793 to 1814, the rate of interest upon these securities was fixed at 3½*d.* per cent per diem, or *5l. 6s. 5½d.* per cent. per annum. Since the last-mentioned year the rate has been progressively reduced to 2½*d.*, 2*d.*, and 1½*d.* per 100*l.* per diem. In October, 1858, the rate was 1½*d.* per diem per 100*l.*, and in May exchequer bills were at a premium of 40 per cent.

The amount of exchequer bills 'outstanding and unprovided for' at the end of each of the last ten years was as follows:—

	£.		£.
1849 . .	17,758,700	1854 . .	22,783,000
1850 . .	17,756,600	1855 . .	26,596,600
1851 . .	17,742,800	1856 . .	28,050,700
1852 . .	17,742,500	1857 . .	25,627,300
1853 . .	16,024,100	1858 . .	25,883,700

EXCHEQUER CHAMBERS. [Court; Exchequer Court.]

EXCHEQUER, THE COURT OF, is a superior court of record established by William the Conqueror, and reduced to its present order by Edward I.

It is the lowest in rank of the four great courts which sit at Westminster Hall, although in ancient times one of the first in importance, as all causes relating to the rights of the crown were there heard and determined, and the revenues of the crown were supposed to be received there.

Etymologists have exhausted much research in ascertaining the origin of the name: some assert that it is derived from the old French word *Eschequier*, a kind of abacus or table; or the German, *Schatz*, 'treasure.' The Latinised form of the word is *Scaccarium*. Camden says it was so called from the covering of the table at which the barons sat being party-coloured or *chequered*, and on which, when certain of the king's accounts were made up, the sums were marked and scored with counters.

The judges of the court of exchequer are the chancellor of the exchequer for the time being, the chief baron, and four other barons, who are created by letters patent, and are so called from their having been originally chosen from such as were barons of the kingdom, the court having been at first formed out of the *Aula Regis*. (Selden's 'Titles of Honour.')

The court of exchequer was formerly held in the royal palace. Its treasury was the great deposit of records from the other courts: writs of summons to assemble the parliaments were issued by its officers; and its acts and decrees, as they related almost entirely to matters connected with the revenue, were not controlled by any other of the ordinary courts of justice.

It now consists of two divisions, one of which exercises jurisdiction in all cases relating to the customs and excise, and other revenue matters generally. The other division, or Exchequer *of Pleas*, is a court of common law, in which all personal actions may be brought and prosecuted. This plea side of the court formerly comprised a court of equity; but by 5 Vict. c. 5, the jurisdiction of the court in equity was transferred to the Court of Chancery.

A plaintiff, when bringing an action in this court, previously to the Act for Uniformity of Process in personal actions (2 Will. IV. c. 39), fictitiously alleged himself to be the king's debtor, in order to give the court jurisdiction in the cause. He added that the defendant owed him money *quo minus sufficiens existit*, to pay the king's debt,—a state of things which the court, out of zeal for the revenue, immediately proceeded to remedy. It is not necessary now to resort to this fiction in order to bring an action in the exchequer; the proceedings of which in personal actions are precisely the same as those of the other superior courts. The procedure in suits, or more properly information, in the crown side of the court have been, by the statutes 22 & 23 Vict. c. 19, closely assimilated to proceedings in an ordinary action.

An appeal lies from this court to the justices of the courts of Queen's Bench and Common Pleas sitting in the exchequer chamber; and from their decision a further appeal to the House of Lords. [COURTS.]

The Court of Exchequer in Scotland was established by the 6 Ann. c. 26. Its judicial powers and duties, after being subjected to various modifications, have been transferred to the Court of Session (2 & 3 Vict. c. 36.

The Court of Exchequer in Ireland was established by the 40 Geo. III. c. 39. Its jurisdiction resembles that of England.

EXCISE DUTIES, the name given to taxes or duties levied upon articles of consumption which are produced within the kingdom. This description, which has usually been given of excise duties, is more strictly applicable now than it was formerly, when the commissioners of excise revenue were also charged with the collection of duties upon various articles imported from foreign countries. Among these foreign articles were wine, spirits, tobacco, glass, and tea. The last named of these was the last that was withdrawn from the management of the Excise and transferred to the Board of Customs. There are still, it is true, certain duties to which the name of excise is applied, which can hardly be called duties upon consumption, although they are accessary to it, such as the duty on sales by auction and the sums charged for licences to permit parties to carry on certain trades.

Excise duties are said to have had their origin in this country in the reign of Charles I., when a tax was laid upon beer, cider, and perry, of home production. The act by which these duties were authorised was passed by the Long Parliament in 1643. This act contains also a list of foreign articles, and among others tobacco, wine, raisins, currants, and loaf sugar, upon which excise duties were imposed, in addition to duties of customs already chargeable. This act was adopted and enforced under the protectorate of Oliver Cromwell; and by the statute 12 Charles II. c. 24, the duties of excise were granted as a part of the revenue of the crown.

For a long time this class of duties was viewed with particular dislike by the people, on account of its inquisitorial interference with various industrial pursuits, and it certainly forms a very strong ground of objection against excise duties, that the security of the revenue which they yield is held to be incompatible with the perfect freedom of the manufacturer as to the processes which he may apply in his works. In every highly-taxed country where consumption-duties form part of the public revenue, it would seem, however, to be hardly possible to avoid the adoption of this class of duties. If, taking for our example an instance which is now exercising an injurious effect in a neighbouring country, it is found expedient to impose a customs' duty upon the consumption of foreign-made sugar, it is clearly necessary, for the protection of the revenue, that an excise duty should be imposed upon sugar of domestic production, otherwise the community at large is made to bear the load twice, once in the form of some other tax, and again to the producer of indigenous sugar, who will charge the consumer nearly as much as he would pay to the importer of foreign sugar, including the amount of the duty. By such means a branch of industry would be fostered, unprofitable to the country at large, and profitable only to the few persons by whom the indigenous sugar is produced, but whose profits will not long continue greater than the usual profits upon the employment of stock obtainable in the same country from other branches of industry. An attempt was made, some years ago, to set up a beet-root sugar manufactory in England, but parliament having imposed an excise duty upon the produce equal to the customs' duty charged upon colonial sugar, the attempt was not successful, which indeed is little to be regretted, for the reason already assigned.

Excise duties are liable to this among other very serious objections, that the regulations under which they are collected are made, perhaps unavoidably, to interfere with processes of manufacture, so as to prevent the adoption of improvements which would be beneficial first to the manufacturer and afterwards to the community at large, which must always be interested in their adoption, because of the greater excellence of cheapness of the products which it is the object of the experimenter to attain. It will give some idea of the extent to which this interference is injurious, if we state, on the authority of a gentleman conversant with all the details of the art of calico-printing, that upon the same premises, with the same capital, and employing the same amount of labour, double the quantity of cloths are now printed which could have been printed previous to the repeal of the duty, and to the consequent withdrawal of the excise officers from the works. Another great objection that may be urged against excise duties is, the facilities which they offer for the commission of frauds against the revenue, an offence which, in the eyes of many persons, is of a venial kind, but which too often ultimately demoralises those by whom it is committed.

In 1845, Sir Robert Peel commenced a reform in the excise laws by repealing those on glass and sugar, and substituting a licence for auctioneers instead of the excise duty on the sale. The duty on bricks and soap was also subsequently removed. In 1849, the Board of Excise was incorporated with that of Stamps and Taxes, under the name of the Board of Inland Revenue. The gross amount of the excise duties in 1844, before the remissions began, was 14,469,366*l.*; in 1858 they amounted to 17,884,300*l.* 16*s.* 3*d.*, from the following sources:—

	£	*s.*	*d.*
Spirits	8,950,195	8	3
Malt	5,412,777	1	8
Licences	1,436,238	17	7
Paper	1,142,113	10	1
Hops	378,320	4	0
Railways	339,568	16	3
Stage carriages	124,993	14	11
Hackney carriages	82,093	14	6
Game certificates	12,228	6	0
Racehorses	5,771	3	0
	£17,884,300	16	3

The excise duties are now confined to hops, malt, paper, spirits, and (beet-root) sugar, of which last none has been brought to charge since 1856. In 1858, of hops there were charged 53,125,101 lbs., of which 4,177,251 lbs. were exported; of malt there were charged 41,605,665 bushels, and 5,049,321 bushels were made free of duty for the use of distillers, and 1,549,213 bushels were exported; of paper there were charged 192,847,825 lbs., of which 16,548,828 lbs. were exported; of spirits there were charged 23,686,751 gallons, 1,096,409 gallons were made free of duty for exportation, and 1,570,548 gallons of that charged were exported. In 1857, 5,190,538 gallons had been exported. On all the quantities exported, which had been subjected to duty, a drawback is allowed, and the malt exported includes the estimated quantity used in beer exported.

The trades in which licences are necessary in order to carry them on, are shown in the following list, with the number of persons in each trade to whom licences had been granted in the year ending March 31, 1858, and the gross amount of tax paid. In some of the trades, as brewers, maltsters, &c., a different amount is paid for the licence, according to the extent of the trade.

		£
Auctioneers	4,358	43,580
Brewers	40,794	81,030
Beer and cider sellers	127,352	304,688
Maltsters and dealers in malt	7,011	19,291
Paper-makers	397	1,642
Soap-makers	369	1,505
Distillers	189	1,963
Rectifiers	157	1,588
Makers of stills	42	22
Chemists using stills	219	110
Spirit-dealers	93,936	560,557
Retailers of sweets	9,896	10,412
Tea-dealers	151,975	84,663
Tobacco manufacturers and dealers	252,048	70,888
Vinegar-makers	69	345
Wine-dealers	34,551	88,765
Retailers of liquors or tobacco on board vessels	365	383
Postmasters	29,247	137,497
Stage-carriage proprietors	7,630	10,695
Hackney-carriage proprietors (London)	5,474	5,474
	766,079	£1,425,098

EXCITANTS. [STIMULANTS.]

EXCITATION, ELECTRIC. [ELECTRICITY, COMMON.]

EXCOMMUNICATION, from *Excommunicatio*, is the highest ecclesiastical censure which can be pronounced by a spiritual judge. This punishment, according to some opinions, had its origin in the advice given by St. Paul when reproving the early Christians for scandalising their profession by prosecuting law-suits before heathen judges; and the apostle accordingly recommended them to leave all matters in dispute between them to the decision of the Ecclesia, or congregation of the faithful. This advice was soon followed, and heathen tribunals were seldom afterwards occupied by the controversies of the Christians.

The bishop and his clergy soon became the judges: the bishop ultimately became sole judge in these disputes. Possessing no coercive powers to enforce his decree, the Courts Christian, as they came to be called, were obliged to adopt the only means of which they could avail themselves to bring the refractory to submission, namely, by excluding them from the rites of the Church, and warning other Christians from their company. A Christian thus shut out from the fellowship of his brethren could not do otherwise than submit.

This censure, although instituted by the primitive church as the means of preserving its purity, and of enforcing obedience to its just laws, was afterwards used for the promotion of ecclesiastical power, and was converted into an engine of the greatest oppression in those countries which were most subject to ecclesiastical rule. (Robertson's 'History of Charles V.,' vol. ii.)

In England excommunication became at a very early period the instrument of punishment of the bishops, and others possessing ecclesiastical jurisdiction. It was divided into the greater and the less excommunication. The latter only removed the person from a participation in the sacraments; the other was called anathema, and not only removed the party from the sacraments, but from the Church and all communication with the faithful, and even deprived him of Christian burial. Subjects were absolved from their allegiance to an excommunicated prince: indeed, they were forbidden to obey him. Gregory V. was the first prelate who ventured to excommunicate a reigning prince, in the case of Robert, king of France, in 998 John and Henry VIII. are well-known instances in English history. The latest instance of all was Napoleon I., in 1809, by Pius VII.

The greater excommunication was hurled against diviners, heretics, their receivers and comforters; simoniacs; violators and plunderers of churches; those who spoiled clerks going to Rome; the plunderers of the property of a bishop which ought to go to his successor; those who gave aid, favour, or counsel to excommunicated persons; and those who laid violent hands on clerks or religious persons, or commanded others to do so. Those punished with the less excommunication were persons committing any mortal sin, as sacrilegious persons; those who received a church from lay hands; notorious offenders; those who talked with, saluted, or sat at the same table with, or gave anything in charity to persons excommunicated by the greater excommunication, unless they were familiars or domestics.

Excommunication was also pronounced for other matters which belong to ecclesiastical jurisdiction, as adultery, incontinence, fornication, &c., or for contempt of any ecclesiastical order or sentence. The sentence was preceded by three monitions at due intervals, or one peremptory, containing the legal space of time, with a proper regard to the quality of the person and the nature of the offence. But, as Blackstone remarks, "heavy as the penalty of excommunication is, considered in a serious light, there are, notwithstanding, many obstinate or profligate men, who would despise the *brutum fulmen* of mere ecclesiastical censures, especially when pronounced by a petty surrogate in the country, for railing or contumelious words, for non-payment of fees or costs or other trivial causes. The common law, therefore, compassionately steps in to the aid of the ecclesiastical jurisdiction, and kindly lends a supporting hand to an otherwise tottering authority." This was effected by the writ "de excommunicato capiendo;" but before it could be granted the contumacy and contempt of the party were to be certified by the bishop to the Court of Chancery by letters under his seal: and by 5 Eliz. c. 23, the writ was made returnable into the King's Bench. The cause of excommunication was also to be stated in the writ, in order that the court might judge as to the justice of the case. The sentence of excommunication might be revoked by the judge who passed the sentence, or upon appeal the party might be absolved. Absolution generally belonged to the same person who passed the sentence, unless in some particular cases, which were referred to the pope or a bishop. (Reeves' 'Hist. of English Law;' Sullivan's 'Lectures.')

By a sentence of excommunication, both greater and less, those denounced were excluded from the right of Christian burial, from bringing or maintaining actions, from becoming attornies or jurymen, and were rendered incapable of becoming witnesses in any cause. But since the 53rd Geo. III. c. 127, excommunication cannot now be pronounced in England, except in certain cases (as spiritual censures for offences of ecclesiastical cognizance); and by that statute, "no person who shall be pronounced or declared excommunicate shall incur any civil penalty or incapacity, in consequence of such excommunication, save such imprisonment, not exceeding six months, as the court pronouncing or declaring such person excommunicate shall direct." The proceedings in those cases, in which excommunication may still be pronounced, are the same, as to the issuing and return of the writ, as they were before the Act of 53 George III. By the same Act, when any person shall refuse to appear when cited by an ecclesiastical court, or shall refuse to obey the lawful order or decree of such court, no sentence of excommunication (except in the cases above alluded to) shall be pronounced; but a writ "de contumace capiendo" shall issue, which in effect is the same as the old writ "de excommunicato capiendo" was. The various difficulties which formerly existed in courts of law with respect to excommunication are thus obviated.

(Blackst., *Comm.*, Mr. Kerr's ed., vol. iii., p. 107.)

EXCRETIN, a substance discovered by Dr. Marcet in the excretions from the human bowels.

EXCRETION. [SECRETION.]

EXCRETOLIC ACID. An olive-coloured fatty acid, found in human excrement. Its composition is not known.

EXECUTION is the effect given to the judgment and other proceedings analogous to judgments of courts of law and in civil suits. This term denotes the process by which a party is put into the actual possession of that to which by the proceedings of a court he appears to be legally entitled.

As a judgment of a court of common law ascertains that the party is entitled to the possession of some subject of a real or personal nature; or to recover damages in respect of property withheld or injuries done, so the execution founded upon such judgment will be framed with a view to putting the party in whose favour the judgment is given either in the actual possession of the thing in dispute, or to enable him to obtain pecuniary compensation.

For this purpose a written command issues in the name of the king or other lord or owner of the court, to an officer of the court: when the judgment is in one of the king's superior courts at Westminster, the officer of the court for this purpose is the sheriff of the county in which the property is situate, or, in the case of pecuniary compensation, the sheriff of the county in which the party from whom such compensation is due is supposed to be.

Where lands or other corporeal hereditaments are recovered, the process of execution is called habere facias possessionem. [HABERE FACIAS POSSESSIONEM.]

A judgment in the action of detinue [DETINUE] establishes the right of the recoveror to the possession of a specific personal chattel, and the writ of execution called a distringas issues, requiring the sheriff to coerce the defendant by his distringas (distress) to restore the specific chattel, or at the option of the plaintiff that he cause to be made of the defendants' goods the assessed value of such chattel. The plaintiff is in either case entitled to recover his damages, costs, and interest in the action.

A judgment for the defendant in replevin [REPLEVIN] establishes his right to the possession of the personal chattel which formed the subject of the litigation. In the ordinary case of an action of replevin after a distress, the right of the defendant in respect of the chattel distrained is merely to hold it as a security for the payment of the debt or duty, the payment or performance of which is sought to be enforced by the coercion of a distress. [DISTRESS.] The writ of execution requires the sheriff to cause the chattel to be restored to the possession of the defendant. This is called a writ de retorno habendo, and in case the sheriff is unable to find the chattel, further process issues commanding him to take other chattels of the plaintiff as a substitute for that which is withheld, by a writ called a capias in withernam.

The most ordinary cases of execution are those in which pecuniary compensation is to be obtained, but in these cases the sheriff is not authorised directly to take money from the party by whom it is to be paid. Formerly the only mode of obtaining this compensation was by process of distringas or distress. But execution of judgments or other records establishing pecuniary claims may now be had by a writ of fieri facias [FIERI FACIAS] affecting the personal property; by writ of elegit [ELEGIT], affecting both real and personal property; and by capias ad satisfaciendum [CAPIAS], by which compliance with the pecuniary demand is enforced by detention of the person of the defaulter in prison until the claim be satisfied, or the adverse party consents to his discharge, or until he be discharged by process of law under the Bankrupt or Insolvent Acts.

A subject is not entitled to pursue all these remedies at once; but in the case of the crown, the right to obtain satisfaction from the goods, lands, and person of its debtor may be enforced simultaneously, by writ of capias, and extendi facias, or extent. [EXTENT.]

Execution is the term applied to denote the giving effect to the sentence of a court of justice. In this sense it is most commonly used with reference to the execution of sentence of death. [SHERIFF.]

EXECUTOR. An executor is he to whom another man commits by will the execution of that his last will and testament. He answers in some degree to the *hæres designatus*, or *testamentarius*, in the civil law, as to the debts, goods, and chattels of his testator; but the origin of executors seems to be properly traceable to a constitution of Manuel Comnenus (*περὶ διοικητῶν τῶν διαϑηκῶν*). All persons who are capable of making a will, and some others besides, as married women and infants, are capable of being made executors; but infants are by statute rendered incapable of acting in the execution of the will until they attain the age of twenty-one.

An executor can derive his office from a testamentary appointment alone, though it is not necessary that he should be appointed by express terms; any words of the testator indicating an intention to make the appointment are sufficient: in this case he is usually called "executor according to the tenor." If no executor is appointed by the will, administration is granted out of the Court of Probate, with the will annexed, in which case the administrator is bound to obey the directions given by the will. An executor may renounce probate; but having once acted, he cannot divest himself of the office or its liabilities; nor can an administrator who has accepted the office, get rid of his responsibility.

An executor may do many acts in execution of the will, even before probate, as paying and receiving debts, &c., but he cannot, before probate, sustain actions or suits. An administrator can do nothing till the letters of administration are issued; for the former derives his power from the will, and not from the probate: the latter owes his entirely to the appointment of the court. If an executor die before probate, administration must be taken out to his testator, with the will annexed; but if an executor, having proved the will, die, his executor will be the executor and representative of the first testator, unless, before proving the will of the second testator, he expressly renounces the execution of the will of the first. If the executor dies intestate, his administrator is not the representative of the testator, but an administrator *de bonis non* of the testator must be appointed by the court. If there are several executors, the office survives, and is transmitted ultimately to the executor of the surviving executor, unless he dies without having appointed an executor. Executors have a joint and entire interest in the effects of their testator; any one of them is capable of acting by himself; and the receipt of a debt, or the transfer of property by one, is as valid as if it had been done by all.

If a stranger takes upon himself to act as executor without any authority, as by intermeddling with the goods of the deceased, he is called an executor *de son tort* (of his own wrong), and is liable to all the trouble of an executor without any of the advantages attached to the office. He is chargeable with the debts of the deceased, so far as assets come to his hands; and is liable not only to an action by the rightful executor or administrator, but also to be sued as executor of the deceased by his creditors and legatees. The only advantage which an executor derives from his office is the right to retain any debt due to him from the testator, as against creditors of equal degree, and this privilege is allowed him, because he cannot take any legal steps to recover payment. This, though practically a privilege, is in reality only a provision of the law that he shall not be prejudiced by his appointment; otherwise as a man cannot sue himself, all the other creditors would, by instituting a suit against the executor, gain priority over him in respect of their debts.

The duties of executors and administrators are in general the same, the only essential difference between them being, as before mentioned, the mode of their appointment. Their duties are to bury the deceased, to prove his will in the proper court, to collect and get in his goods and chattels, to pay his debts in the order appointed by law, and also his legacies, if he has bequeathed any, and to dispose of the residue of his goods and chattels in the manner by the will directed, or according to the statutes for the distribution of the effects of intestates, if there should be a total or partial intestacy. Executors and administrators are liable to an action at law, and also to a suit in equity, for the payment of the debts and liabilities of their testator or intestate; and to be sued for the legacies bequeathed by him, and the due administration of his estate: but no action at law lies for a legacy, at least not until after the executor has assented to it, as it is called, that is, has acknowledged the sufficiency of the assets after providing for the payment of the debts. [LEGACY.]

It appears to have been a subject of much controversy whether the probate of wills was originally a matter of exclusive ecclesiastical jurisdiction, but whatever may have been the case in earlier times, it is certain that until the passing of the 20 & 21 Vict. c. 77, the Ecclesiastical Courts were the only courts in which, except by special prescription, the validity of wills of personalty could be established or disputed. By that act the ancient jurisdiction of those courts, in matters of probate and administration, was transferred to a new court thereby established and styled "The Court of Probate." A will should be proved within six months after the death of the testator, or within two months after the termination of any dispute respecting the probate. (See 55 Geo. III. c. 184, sec. 57.)

Executors and administrators are treated by the courts of equity as trustees for the creditors, legatees, and next of kin of their testators or intestates. They are bound to administer the assets according to their due order of priority, and to pay the debts of the deceased in like manner. The probate is exclusive evidence of a will of personalty; but courts of equity assume the jurisdiction of construing the will in order to enforce the performance of the trusts by the executor: hence they are sometimes styled courts of construction, in contradistinction to the Court of Probate. Formerly, the personal estates only of persons deceased were liable for the payment of their simple contract debts; but now, since the statute 3 & 4 Will. IV. c. 104, real estates are liable for the payment of debts of that nature; and it may be broadly stated that all the real and personal estates of the deceased are assets for the payment of his debts. The personal estate is liable in the first instance, unless the testator direct otherwise. Estates descended are applied before estates devised; and in other respects the estates of the deceased are administered in the order laid down by the courts.

The debts are also payable in a certain prescribed order. 1. The funeral expenses, the expenses of probate, and the costs of a suit for the administration of the estates, if any be instituted. 2. Debts due to the crown on record or specialty. 3. Certain debts, which by statute are to be preferred to others, as poor-rates, by stat. 17 Geo. II. c. 38, &c. 4. Debts of record, as judgments, statutes, and recognisances. 5. Specialty debts, that is, debts due on bonds or instruments under seal. 6. Simple contract debts, as upon bills of exchange and ordinary verbal engagements. It seems that in this class debts due to the crown and the wages of domestic servants are entitled to priority.

The executor must pay the debts in the order mentioned; for if he apply the assets in payment of those of a lower degree, he will be personally answerable, to the extent of the assets misapplied, to the creditor of the higher degree. He may, however, pay a debt of an inferior degree before one of a superior, provided he has no notice of the latter, and a reasonable time has elapsed after the testator's death; except in the case of debts of record, of which the executor is bound to take notice. An executor or administrator may also retain his own debt as against creditors of an equal degree; and he may pay any one or more debts to creditors of equal degree, although thereby he may exhaust the assets, unless a suit or action be commenced against him; and even in that case he may, by confessing a judgment, enable a creditor to obtain priority. But notwithstanding an action or suit be commenced, he may pay a creditor of a higher degree than the one proceeding against him; save only where the suit is for a general administration of the estate, when the executor should not make any farther payments.

The debts being all paid, the next duty of an executor or administrator is to pay the legacies, and distribute the personal estate to the next of kin of the testator if there be any overplus; but where the testator has made a residuary legatee, he is entitled to the surplus. If the assets are not sufficient for the payment of the legacies, the executor must pay to each legatee an equal proportion of his legacy, unless the testator has directed the order of payment, in which case the legacies must be paid in full in the prescribed order, and the whole loss must fall upon the last in order. Specific legatees, that is, persons to whom a specific fund or article of property is given by the will, are not liable to abatement of their legacies, but receive the fund or article whether the assets are or are not sufficient to pay the other legatees; though if the fund is changed, or the article sold, or from any other cause is not in existence at the death of the testator, the legacy fails, or in technical language is said to be adeemed. Executors and administrators cannot be compelled to pay legacies or distribute the personal estate before the expiration of a year after the decease of the testator; and not even then, if notice has been acquired or there is reasonable ground to suspect the existence of debts and liabilities. Indeed, unless the assets are of ample amount, the executor or administrator should not pay within the year, even though the testator has directed it to be done; for it has been held that such a payment affords no defence against a creditor, and the testator or intestate may be bound by covenants upon which subsequent liabilities may accrue; or he may have been a trustee, and some maladministration of the trust estate may be discovered after the lapse of many years. In these and many other cases, executors and administrators should not part with the assets until all chance of liability is at an end, or security be given by the parties receiving them to refund in case of need. This last course will sometimes be directed by a court of equity in a suit for a legacy; for though an executor or administrator may recover from the legatees or next of kin to whom he has handed over the assets in case of subsequently-discovered debts of the deceased, it is obvious that this is a very insufficient and uncertain security. Where a legatee is an infant, or the testator has directed his executors to invest any portion of his estate in the funds, or has provided for some future payment to be made, or from any other cause, an investment by the executors becomes necessary, they are, in the absence of any express direction to the contrary, bound to make such investment in the Three per Cent Consols, that fund being considered by the Court of Chancery as the most desirable for the purpose of investment. The rule is inflexible, and an executor who should disregard it would run great risk of having to pay the costs of a suit to compel him to place the money in that fund, and to make good any loss which might occur through the change of securities.

Full information upon these subjects will be found in the valuable work of Mr. Justice Williams, on the law relating to Executors and Administrators; and in Jarman on Wills, and Powell on Devises.

EXE'DRA (ἐξέδρα), a name given to certain open chambers or recesses in the buildings of the ancients. There were numerous exedræ in the baths. Vitruvius says the spacious exedræ of the Greek palæstra were furnished with seats. The exedræ were placed in the three porticos of the palæstra. (Vitruvius, v. c. 9.) Sometimes in houses a covered hall, and of a square form, was called exedra. (Vitruvius, vi. cap. 5.) In the disposition of the Greek house the exedræ were placed looking to the west. (Vitruv., vi. cap. 10.)

EXEMPLIFICATION. [RECORD.]

EXERCISE. [ANALEPTICS.]

EXETER or EXON DOMESDAY, the name given to a record preserved among the muniments and charters belonging to the dean and chapter of Exeter Cathedral, containing a description of the western parts of the kingdom, comprising the counties of Wilts, Dorset, Somerset, Devon, and Cornwall; supposed, as far as it extends, to contain an exact transcript of the original rolls or returns made by the Conqueror's commissioners at the time of forming the General Survey, from which the Great Domesday itself was compiled. It is written on vellum, in the form of a book of the small folio size, containing 532 double pages. The skins or sheets of vellum of which it is composed vary in the number of leaves which they comprise from one to twenty; the lands of each of the more considerable tenants beginning a new sheet, and those of almost every tenant a new page. The lands in the counties of Devon, Somerset, and Cornwall belonging to one tenant are classed together, the counties following each other, though not always in the same order; and, in like manner, the summaries of property in Wilts and Dorset are classed together.

The manuscript begins with the "Inquisitio Geldi," or taxation of the hundreds of Wiltshire, of which it contains no less than three copies, the third seeming to be a corrected edition of the other two. The taxation of the hundreds of Dorsetshire follows, and after it those of Devonshire, Cornwall, and Somersetshire. The Inquisition for each hundred states—1, the total number of hides; 2, the number held by the king and his barons in demesne, with an enumeration of those for which the tax was not paid; 3, the number of hides for which the tax was paid, and its amount; 4, the tax in arrear, and the reasons for its so remaining. Throughout, the geld or tax is computed at the rate of 6*s.* for every hide.

Upon collating the returns of lands which form the great body of the Exeter Survey with the Exchequer Domesday, they have been found, with a few trifling variations, to coincide; one entry of property alone being discoverable in the Exeter which is omitted in the Exchequer Domesday, relating to Sotrebroc in Devonshire. The Exeter manuscript, however, is not complete in its contents. There are considerable omissions of lands in Wiltshire, Dorsetshire, and Devonshire; but these have evidently been cut out and lost. In Cornwall every manor mentioned in the Exchequer occurs in the Exeter Domesday. One leaf of this record was accidentally discovered in private possession within these few years, and has been restored to the manuscript. In the spelling of the names of places and persons there is a remarkable difference between the two records. The names of tenants in King Edward's time are far more numerously preserved in the Exon than in the Exchequer Domesday. In the systematic arrangement of the subject matter, the Exchequer Domesday bears unquestionably a decided preference over the Exon Domesday. Occasional insertions in the margin of the Exon Survey are entered in the text in that of the Exchequer. The lands of the great barons, also, in the Exon Survey are in a few instances intermixed. In folio 161 of the Exon, although the title of the lands described is "Terra Abbatis Glastingheberiensis in Devenescira," yet in fact there is only one of the manors in that county; the rest are all in Somersetshire, and are entered as such in the Great Domesday. On the contrary, in folio 194 of Exon, the "Terræ Ecclesiarum quæ datæ sunt Sanctis in elemosina," from all that appears on the face of the record are in Somersetshire, whereas they are really in Devonshire, and are so placed in the Exchequer Domesday.

The most striking feature, however, of the Exeter Domesday, in which it uniformly supplies us with additional knowledge to that in the Exchequer Survey, is the enumeration of live stock upon every estate; there is an account of the number of oxen, sheep, goats, horses, and pigs, exactly in the same manner as it is given in the second volume of the Great Domesday. The reason for omitting this enumeration in the breviated entries of the first volume of the Great Survey is self-evident. The live stock was altering every day and year; the enumeration of it, therefore, could be of no further use than for the exact time when the survey was made. A comparison of this part of the Exeter with the second volume of the Great Survey tends greatly to corroborate the notion that the returns of the counties of Essex, Norfolk, and Suffolk, were transcribed in full from the original rotuli, in the same manner as the Exeter Domesday. The difference between the two surveys as to diction, when they agree in sense, is likewise remarkable.

The utility of this record for the purpose of comparison with the Exchequer Domesday is obvious. The Exeter Domesday was published with several other surveys nearly contemporary, by order of the Commissioners upon the Public Records, under the direction of Sir Henry Ellis, in a volume supplementary to the Great Domesday, folio, London, 1816.

EXHAUSTING SYRINGE. [Air-pump.]

EXHAUSTIONS, METHOD OF. [Geometry of the Greeks.]

EXHIBIT. A deed or writing proved by a witness or admitted by the parties to a suit in court. The documents attached to affidavits, as referred to in or verified by them, are also termed exhibits.

EXHIBITIONS, INTERNATIONAL. The international exhibitions of the last few years, in London, Dublin, New York, and Paris, following the national exhibitions held in these or other places, have had an important influence on the advancement of manufacturing art, and in the application of tasteful design to articles in every-day use. How far this influence has extended may be a disputed point; but no thinking person can regard it as otherwise than beneficial, so far as it goes. It may be well therefore to give brief notices of the principal of these exhibitions, beginning with that at Hyde Park in 1851.

Great Exhibition of 1851. This was the first international display of manufactures; the first exhibition of the industry of all nations.

The proposition for a great exhibition of national manufactures to be held at intervals of three or more years seems to have originated in 1845 with the Society of Arts, of which Prince Albert was president. On its first announcement the project was coldly received, and some three years were suffered to elapse before it was again brought distinctly before the public. Meantime the annual exhibitions of the society were rendered more attractive, and manufacturers and commercial men began to feel increased interest in the proposal. By the beginning of 1849 the council of the society had matured a plan, of which, in March of that year, they published an outline. The society now petitioned parliament for pecuniary aid. Prince Albert, who had all along warmly supported the proposal, conceived that the time had arrived for imparting to it a much more magnificent form, by throwing the exhibition open to the industry of the world. The council adopted his suggestion, and measures were taken for enlisting in behalf of the scheme the sympathies of manufacturers. The idea of an international exhibition of industry at once seized the general mind. At the preliminary meeting held in the city under the presidency of the Lord Mayor for the purpose of publicly enunciating the scheme, it was received with the utmost favour, and the provinces speedily gave in their cordial adhesion. Upon the suggestion of Prince Albert, application was made to the government for the appointment of a royal commission for managing an exhibition of the works of industry of all nations; and a royal warrant was accordingly issued in January, 1850, appointing such a commission, with Prince Albert as its president. At the first meeting of the commission, a provisional contract which had been entered into with Messrs. Munday, for erecting a building, was annulled on terms mutually arranged; and plans on a much larger scale were laid. The commissioners now appointed (January 24) a building committee, to whom was entrusted the entire arrangements for providing a suitable edifice. On the 25th of January a great meeting was held at the Mansion House, at which the hearty adhesion of various influential merchants and manufacturers was announced, and a general subscription was inaugurated with a view to raising funds for meeting every kind of outlay connected with the undertaking. It was followed by corresponding meetings in every part of the country, and it was soon made evident that ample funds would be furnished. In fact a total of very nearly 80,000*l.* was ultimately reported to the commissioners as subscribed, though only 67,896*l.* were paid into their bankers—upwards of 11,200*l.* having been somehow absorbed in the several localities as expenses. On the 21st of February, the commissioners were able to make a public announcement of the general plan of the exhibition, and to communicate the royal permission to hold it in Hyde Park.

The site granted for the building was on the south side of Hyde Park, between Kensington Drive and Rotten Row. The commissioners announced that the building would cover an area of from 16 to 20 acres; that it must be ready for the reception of goods by the 1st of January, 1851; that from that day to the 1st of March following goods would be received; and that the Exhibition would be open to the public on the 1st of May, 1851. In March 1850 the Building Committee appealed to architects and engineers to assist them with sketches and suggestions as to the form and general arrangements of the building required for the Exhibition. This appeal was responded to by a large number of professional men, including several foreign architects. The commissioners, however, were unable to recommend any one of the designs for adoption, and ultimately Mr. (now Sir Joseph) Paxton proposed an entirely new plan, that of a vast building of iron and glass resembling in its general principles the great conservatory he had constructed for the Duke of Devonshire at Chatsworth. With the general public it from the first became popular, and as soon as the contractors, Messrs. Fox and Henderson, undertook its erection upon terms which removed all doubt of its economy as well as practicability, the commissioners determined upon adopting it, and accepted Messrs. Fox and Henderson's tender. They were to receive 79,800*l.*, and the materials of the building were to remain their property.

From this time all proceeded rapidly and smoothly. The contract was signed on the 26th of July; on the 30th the contractors obtained possession of the site; on the 26th of September the first column of the building was erected, and on the 4th of December the first rib of the transept was raised; by the 31st of December the building was sufficiently advanced to allow of a lecture being delivered within it to the members of the Society of Arts; and on the 3rd of February, 1851, the completed building was formally handed over to the Executive Committee.

Its entire length was 1851 feet—its breadth 408 feet, with an additional projection on the north side, 936 feet long by 48 wide. The central portion was 120 feet wide by 64 high; on either side of this was another portion 72 feet wide by 44 high; and the north and south portions were 72 feet wide by 24 high. The whole building, from the ground-plan to the ridges of the roof, was a repetition of certain regular forms; and, one portion having been first thoroughly modeled, was a matter of simple arithmetical calculation, and consequently from the hour when the contractors commenced their work, from the simplicity of the plan and the singularly small number of castings required, all the parts were prepared and adjusted to each other with almost mechanical regularity and precision. The colouring of the building was entrusted to Mr. Owen Jones, already well known by his works on the Alhambra. How admirably the building answered its purpose, what new and elegant combinations of form, light, and shade and colour, both the exterior and interior offered to the eye, or what a magnificent and surprising appearance it presented as a whole, whether regarded externally, or when, looking down its unrivalled vista, with its rich and varied contents, from one of the end galleries, few of our readers need to be told.

As soon as provision had been made for the building, the commissioners turned their chief attention to the means necessary for obtaining its contents. The outline of an elaborate system of classification, drawn up by Dr. Lyon Playfair, was issued, showing what a wide range of articles was sought to be brought together under the title of 'Objects of Industrial and Productive Art.' The whole was arranged under four great sections: Raw Materials, Machinery, Manufactures, and Fine Arts; and these were divided and subdivided into a vast number of classes and smaller divisions. To facilitate the collection of the objects, and to serve as ready means of intercourse between the producers and the commissioners, district committees were formed in all the principal towns and manufacturing localities, by whom all the arrangements respecting the allotment of space in the building and the transmission of the goods were conducted. Formal communications were made to the various foreign governments, as well as to the governors of British colonies, by most of whom commissioners were appointed to conduct the operations in those countries required for their adequate representation in the great undertaking. And so judicious were these several arrangements, that though from almost every country in Europe—from almost every state in the North American Union—from the republics of South America—from each of our own wide-spread colonies—from India, Egypt, Persia, and even from the Society Islands, specimens more or less bulky, valuable, and numerous were sent, the numbers were comparatively few that reached their destination materially later than the date at first fixed for their arrival. Considering the entire novelty of the whole proceeding, the immense difficulty there must have been in many instances experienced in getting the collections together, the little knowledge that a large proportion of the contributors could have had of the extreme importance of punctuality, as well as their comparative want of interest in the success of the scheme, and the various physical as well as conventional obstructions which had to be encountered, this must, we think, be regarded as by no means one of the least remarkable circumstances connected with the successful issue of the whole.

Of the actual number of objects exhibited no record was kept. Of their value, many wild guesses were hazarded during the continuance of the Exhibition; the commissioners state in one of the appendixes of their Report that, taking in each case the owner's estimate of the value of his possession, the gross value of the articles exhibited—the famous Koh-i-noor being alone excluded from the reckoning—was under two millions (1,781,929*l.* 11*s.* 4*d.*). The total number of exhibitors was about 15,000.

The Exhibition was formally opened by her Majesty, on the first of May, 1851; it remained open 144 days, being finally closed on the 11th of October. The entire number of visits paid to the Exhibition was 6,063,986, being a daily average of 42,111. This average was not reached till June, but from that time till the close of the Exhibition there was comparatively little variation till the last week, when the average was doubled. The number of visitors during this week was so extraordinary that we are tempted to set down the figures in detail. Monday, October 6th, 107,815; Tuesday, 109,915; Wednesday, 109,760; Thursday, 90,813; Friday, 46,913; Saturday, 53,061.

The six million visits paid to the Exhibition plainly indicate but very roughly the actual number of visitors. Some persons went doubtless ten or even twenty times during the season, a very large proportion went twice. After weighing carefully the probabilities of the case, the authorities arrived at the conclusion that the probable average of visits would be about three, and that consequently about two millions of persons visited the Exhibition. Further, an attempt was made to arrive at the number of *foreign* visitors; and this inquiry led to the unexpected result that not much above 40,000 foreigners visited England beyond the usual annual number of about 15,000. As concerns London and country visitors, an inference was drawn that the number of persons who came from the provinces to view the Exhibition slightly exceeded a million: roughly, we may say that the Exhibition was visited by about a million of the inhabitants of London, the same number from the provinces, and about 50,000 foreigners.

The details of the jury awards do not come within our present object; but the following are the general results, as affording materials for comparison. There were 166 "Council Medals," 2876 "Prize Medals," and 2042 "Honourable Mentions," making a total of 5084 honorary distinctions of all kinds. If we take the exhibitors at the estimated number of 15,000, about one-third were deemed worthy of some kind of recognition. Of the total number, 2039 were taken by exhibitors belonging to the United Kingdom, and 3045 by foreign exhibitors. Our foreign guests occupied about two-fifths of the space, and took off three-fifths of the honours. The greatly-coveted "Council Medals" were awarded in the ratio of 79 to British and 87 to foreign exhibitors; the "Prize Medals," 1244 British and 1632 foreign; the "Honourable Mentions," 716 British and 1326 foreign.

In relation to different classes of exhibited articles, there were a few striking and instructive facts. In machinery, in manufactures in metal, and in glass and porcelain manufactures, the British exhibitors gained more prizes than all the foreigners combined. In textile fabrics, in fine arts, and in miscellaneous manufactures, the foreign exhibitors took off the honours in the ratio of about three-fifths to two-fifths British. But in the section of raw materials for food and manufactures, the foreign exhibitors gained nearly *four times* as many prizes as the British (988 to 262). The great honours, the Council Medals, were very unequally distributed as regards the classes of exhibited articles; for out of the whole number of 166, no less than 88 (more than one-half) were awarded for machinery alone. This is a significant fact; showing that the Juries, or rather the Council of Chairmen, were not deterred by the gorgeous display around them from doing justice to the great working agencies by which modern wealth is produced.

We must devote a paragraph to the Financial results. The receipts at, and in relation to, the Exhibition, by which it was made a self-supporting concern, were truly remarkable. The total receipts amounted in round numbers to 506,000*l.*, that amount being thus made up: subscriptions, 67,800*l.*, admission fees 425,000*l.*, casual receipts (that is, refreshment and catalogue contracts, royalty on medals, washing-rooms, &c.) 13,200*l.* The total expenditure connected with the Exhibition was about 330,000*l.*, leaving a surplus of 176,000*l.* in the hands of the commissioners; but the final balance, including interest on Exchequer Bills and additional small receipts was 186,436*l.* How to apply this large surplus was a most important question, and they arrived at the conclusion that instead of applying it to any purposes of a temporary, partial or local character, they could in no way so properly act in the spirit of the pledges held out to the public as by assisting in carrying out a comprehensive scheme which should have for its object to "increase the means of industrial education and extend the influence of science and art upon productive industry." Properly to carry into execution any comprehensive scheme would require the liberal co-operation of the public and the government. The sum in the hands of the commissioners would go but a small way towards meeting the requirements of the case. It would suffice however to prepare the ground, and they determined so to employ it, leaving it to the public to complete the work when its importance and necessity shall have become fully understood and appreciated.

Acting on the suggestions of this report, the government in the speech from the Throne at the opening of the session of 1852-53 invited the "aid and co-operation" of parliament in promoting a "comprehensive scheme" for the advancement of the Fine Arts and of Practical Science, which was in effect the scheme of the commissioners. After some discussion the House of Commons voted the sum of 150,000*l.* towards the purchase of a site on which a National Gallery and Museum might be erected, and which should be available for the other purposes indicated. An equal sum was provided by the commissioners out of the surplus remaining at their disposal. The land purchased by the commissioners consisted of the well-known Gore House estate of 21 acres, situated nearly opposite the site of the Exhibition of 1851; the Villars estate of 48 acres, and some other adjacent land, which "were deemed indispensable for the completeness and development of the capacities of the property." Altogether it formed a compact estate of about 86 acres, its extreme length being half a mile, its average width a quarter of a mile. The commissioners were anxious to secure other adjoining property to the extent of about 80 acres then obtainable, making in all about 170 acres, but the Government demurred, and the opportunity was lost, it being speedily purchased for building purposes. For the completion of the purchases the government subsequently obtained an additional vote of 27,500*l.*; and the commissioners, having obtained the necessary powers from parliament, have formed upon the estates lines of road, sewers, &c., retain, in their hands a balance for the purpose of meeting current expenses and providing for contingencies. The commission itself has been incorporated as a permanent body, and certain members of the government are now *ex officio* members of it.

The "comprehensive scheme" of the commissioners proposed eventually to bring together, upon the locality they have purchased, all the existing metropolitan institutions, whether dependent on government or on private support, which have in view the advancement of science and art in their various branches, and to "establish a central point of union for those who in so many ways devote their energies to the same ends, especially in respect to the practical application of science and art to productive industry." But the commissioners have been doomed to see their scheme reduced to much humbler dimensions than that in which it at first presented itself to their imagination; their projects relating to the National Gallery, the British Museum, the National Botanic Collection, &c., have not down to the present time (Jan., 1860) been acted upon. Nevertheless a very definite advance has been made. By manufacturers and artisans, and by general public, as well as by the commission, the great importance of the systematic art instruction is now generally admitted. A new department of the government has been created, whose special duty is the promotion of Industrial Art and Science; and to which was intrusted the direction of all previously existing government scientific and art institutions, and the encouragement of all local institutions of a similar order. It does not fall within the scope of the present article to trace further the operations of the commissioners or the department. [Science and Art, Department of.]

Dublin Exhibition of 1853.—The Crystal Palace of Hyde Park—perhaps (on various grounds) the most world-renowned building of the present century—passed into the hands of Messrs. Fox and Henderson after the close of the Great Exhibition; they sold the materials to a joint-stock body—the Crystal Palace Company. By this company nearly *one million and a half sterling* has been expended on the Crystal Palace and grounds at Sydenham; but it does not fall within the limits of the present article to notice the exhibition at Sydenham, however remarkable in many respects it may be. We pass on therefore to notice the Dublin Exhibition of 1853, which, although occasioning a loss to its projectors, brought well-deserved credit to Ireland and the Irish. The general principle of international exhibitions having just been pretty fully treated, we shall only present here a mere outline.

The Royal Dublin Society had long been accustomed to hold triennial exhibitions of Irish arts and manufactures at their house in Merrion Square. The city of Cork held a similar exhibition in 1852. The pleasure afforded in both of those cities, coupled with the great success of the Hyde Park Exhibition in 1851, led to the suggestion of some more extensive scheme for the year 1853. Mr. William Dargan, a wealthy and liberal railway contractor, wrote to the Dublin Society, proposing that a large exhibition building should be constructed on the lawn in front of the Society's house; that a special executive committee should be appointed to manage a grand exhibition; that he himself would advance the sum of 20,000*l.*; that he would take the building at a valuation after the close of the exhibition; that if, after payment for the building and all other expenses, the proceeds of the exhibition should not amount to 20,000*l.*, with interest thereon at 5 per cent., he should receive the proceeds, less all the expenses incurred, but that if the proceeds should be more than equivalent to all these claims, the surplus should remain at the disposal of the committee. This liberal offer was at once accepted, and a committee appointed. The committee advertised for plans for a building, and selected from a large number one which was sent in by Mr. Benson. Suggestions being from time to time made for various extensions of the plan, Mr. Dargan, in the same generous spirit as before, increased his liability to 40,000*l.* The building was constructed during the winter and spring. It comprised a central hall, 425 feet long, 100 feet wide, and 105 feet high, with a waggon-vaulted roof, terminated by domes at the two ends, and lighted by skylights on the top. There were lesser halls on either side of this central hall, and still smaller halls bounding the building on the north and south. There were, in addition, several subsidiary halls and galleries; and all were tastefully painted in coffered panelling. On the 12th of May, 1853, the exhibition was opened by the lord lieutenant. Nothing but the desire of keeping faith could have warranted the opening on that day; for, although the building itself was nearly finished, the contents and arrangements were very incomplete. Indeed, the collection was constantly being added to throughout the whole duration of the exhibition.

The building contained a fine collection of pictures; contributions in art and manufactures from several foreign countries; a fair amount of specimens illustrative of English and Scottish industry; and a larger collection than had ever before been made of the produce, manufactures, and art of Ireland. That Ireland's contributions did not show such an advanced degree of excellence as those of the sister-country was to be expected; but they had this value,—that they marked the state of things in 1853, and that, by showing wherein the industrial deficiencies of the country chiefly lay, they suggested the road to improvement. The exhibition building cost 48,000*l.* The value of the contents, at the fullest period, was roughly estimated at somewhat over 500,000*l.*, of which the fine arts specimens (paintings, sculptures, and mediæval productions) were set down at 200,000*l.* The exhibition closed on the 29th of October. The result, however, gratifying in many ways, was far from successful financially, seeing that a heavy loss fell on Mr. Dargan.

New York Exhibition of 1853.—It was perhaps unfortunate for both cities that the exhibitions at Dublin and New York took place in the same year; for this coincidence distracted the attention of many who might have been willing to contribute. In both cities the exhibition took place without the direct aid of the government; but New York was not so fortunate as Dublin in obtaining the noble offer of one man to bear whatever loss might occur. The American visitors to the Hyde Park Exhibition took home with them recollections which led them to wish for something of a similar character in their own country. Many conferences were held, chiefly at New York; and towards the close of 1851 the municipal authorities of that city agreed to grant, to a joint-stock company established for the purpose, a lease for five years of a plot of ground called Reservoir Square, close to the magnificent reservoir terminating the Croton aqueduct. The ground was to be rent free, on two conditions: that the exhibition building constructed thereon should be of iron and glass; and that the fee of admission for visitors should on no days be higher than half a dollar (2*s.* 1*d.*). The legislature of the state of New York granted a charter of incorporation to the company; and the customs authorities agreed that the building should be regarded as a bonded warehouse, into which articles might be brought duty free during the continuance of the exhibition. Thus armed, the directors of the new company met in March, 1852; they announced an issue of shares to the amount of 300,000 dollars (60,000*l.*); this capital was readily subscribed, and the total was afterwards raised to 500,000 dollars (about 100,000*l.*).

It was soon found that the choice of locality was bad; the spot was three or four miles from the heart of the city, and comprised an area of only about 450 feet square,—far too small for the purpose in view. The directors advertised for plans. Sir Joseph Paxton sent in one, which was much admired for its beauty, but which was unsuited to the shape of the ground. Among many competitors, a plan of Messrs. Gildermeister and Carstensen was accepted. The building was in the shape of a Greek cross, about 400 feet in each direction, with arms 150 feet wide. In the centre was a circular space 100 feet in diameter, covered by a dome. Each arm of the cross comprised nave and aisles, with galleries over the latter. The most attractive part of the interior was the beautiful dome, 123 feet in diameter, framed on 32 very ornate ribs of iron, and having 32 windows of stained glass alternating with the ribs. The windows in the main building were rendered translucent by the use of glass having a thin vitrified layer of white enamel. There were octagonal towers at the four corners of the cross, and twelve staircases to lead from the ground-floor up to the gallery. The exterior was painted bronze-colour, slightly relieved with gold; the interior was mostly cream-coloured, picked out with the three positive colours—red, yellow, and blue. In the struggle for more space, the directors found themselves able to construct a strip of building, 450 feet by 75, on one side of the Greek cross.

Agents were sent over Europe to invite contributions; and the builders did their best to finish the structure by the 1st of May, 1853, the day appointed for the opening; but numerous difficulties supervened, and the opening did not take place till the 14th of July. This delay was disappointing to the exhibitors and the public, and disastrous to the company, seeing that it seriously limited the number of summer days available for the exhibition. Even on the day last named the whole arrangements were in a chaotic state; the "machinery in motion" and the picture-gallery were not opened till September 1st. The articles were grouped in 31 classes (one more than at the London Exhibition, by separating the musical from the philosophical and horological instruments); but the size and shape of the building did not afford much facility for geographical grouping—so remarkable a feature in Hyde Park. There were prize medals, and jurors to award them; but the juries were 17 instead of 31. There were about 4800 exhibitors, of whom rather less than one-half belonged to the United States; the rest being foreigners, mostly from Europe. The Exhibition was open 119 days. During this time the receipts, from visitors, sale of catalogues, &c., were 340,000 dollars, or about 71,000*l.* This result was very unsatisfactory. The company spent 540,000 dollars on the building, 100,000 dollars on the fittings and furniture, and 250,000 dollars in miscellaneous outlay, during a period of more than two years. The final cost, for everything, was very little short of 200,000*l.* It absorbed all their share capital, all the receipts from visitors, and two loans raised at interest. What they had *per contra* was the exhibition building, and the liberty to use the building and its site for exhibition purposes during a further period of four years.

The British government sent over commissioners to the New York Exhibition, chiefly for the purpose of examining and reporting on the quality of the articles exhibited. The commissioners, like the exhibitors, were wearied by the delay in opening; and they fully admitted that the display would have been both superior and more remunerative if the contractors could have finished the building in due time. By far the most valuable feature was the exhibition of machines made in the United States; these were extensive, varied, and excellent, and attracted much attention on the part of the English visitors. The British government purchased numerous machines used in the manufacture of rifles, pistols, and carbines.

Paris Exhibition of 1855. The French government soon after the close of the grand display in London, resolved on the holding of an international Exhibition at Paris, based upon similar principles; but various circumstances prevented the realisation of the scheme until 1855. The whole cost was borne by the government, instead of by visitors' payments, as in England. The management was confided to a special commission appointed by the Emperor. The building constructed, however, in the Champs Elysées, and called the *Palais de l'Industrie*, belonged to a joint-stock company; it was commenced on the understanding that the government would guarantee 4 per cent. on the outlay, together with a share in the surplus profits; but as a surplus never appeared, the whole of the admission money paid by the visitors went to the company. Among the commissioners were comprised many names of European reputation — Elie de Beaumont, Dupin, Gasparin, Ingrés, Leplay, Lesseps, Merimée, Chevalier, Morin, Poncelet, Regnault, Sallandrouze, Visconti, &c. One of the points of difference between the London and Paris Exhibitions was the admission of paintings and engravings into the latter. In addition to France and her colonies, 53 foreign states, and 22 colonies belonging to those states, sent articles for exhibition. In the latest edition of the official catalogue, there appeared the names of 20,839 exhibitors; of whom 10,691 were French, and 10,148 foreign. England and her possessions figured for 2574. It required 6400 packages, weighing 1300 tons, to take the British goods only to Paris.

The building was not of a compact and uniform kind, like Paxton's palace of glass in London. There was a Palais de l'Industrie, and there was a Palais des Beaux Arts; there was a building called the Panorama; and three smaller buildings were subsequently added, for the reception of agricultural implements, carriages, and cheap articles. There were also exhibiting spaces in open ground; and thus it happened that the articles exhibited occupied altogether seven or eight different localities. The main building was of stone, brick, and glass, much more costly than the Hyde Park building, and intended to be more permanent; it was, however, only 800 feet long by 350 wide. Although the block of buildings was pierced by 400 windows, it was not so well suited as the glass palace in Hyde Park for the display of goods. When it was clearly seen that this building would be too small, two others were hastily erected; one, for machinery, was a gallery of immense length running along the north bank of the Seine; and the other, for a picture gallery, or Palais des Beaux Arts, was a wooden building in the Allée des Veuves. Altogether, the various buildings, together with the other expenses connected with the undertaking, involved the very large outlay of one million sterling; but Mr. Cole, one of the British commissioners, was informed, on good authority, that this sum was more than equalled by the extra expenditure of foreigners in Paris during those months.

Owing partly to the substantial nature of the main building, and partly to difficulties between the government and the owners of the Palais de l'Industrie, the exhibition was not open till the 15th of May; it was closed on the 15th of November. The total number of visits paid was 4,533,464 (the Hyde Park number was about one-third more). About 40,000 British subjects were among the visitors. Unlike its English predecessor, the exhibition was open on Sundays as well as week days; Sunday was, indeed, the "peoples' day," on which the charge for admission was only 20 centimes (2*d.*); Friday was a special day, on which the charge varied from 2 to 5 francs (1*s.* 8*d.* to 4*s.*), at different times during the autumn; on the other five days of the week the charge was uniformly 1 franc (10*d.*). On one particular Sunday (May 27th) the exhibition was thrown open gratuitously. There was only one kind of season ticket, charged at 50 francs (2*l.*). Two sections of the exhibition,—the Palais de l'Industrie and the Palais des Beaux Arts—were distinct, and subject to separate charges for admission; the visitors to the former were four times as numerous as those to the latter.

The articles were classified nearly in the same way as in London, there being in each case 30 classes altogether. To apportion medals to deserving exhibitors was the difficult labour of nearly 400 jurors, of whom about half were named by the French government, and the other half by foreign governments. The foreign jurors found this work to be a great tax on their time, seeing that they were thus engaged during the greater part of three summer months. There were four classes of medals distributed, and one grade of "honourable mention."

In relation to the British portion of this exhibition, it may be stated that the government placed the sum of 50,000*l.* at the disposal of the Board of Trade, to assist in defraying the expenses incurred by the exhibitors, and in preparing reports on the results of the exhibition. These reports have since been published by the government at a very cheap rate: they are about 30 in number, and were drawn up by some of the English jurors who had taken an active part in the onerous labour of examining the articles exhibited. The three portable volumes containing the reports constitute a valuable addition to the literature of the industrial arts.

Zollverein Exhibition at Munich.—The example set in 1851 has led to the organisation of many other industrial displays in the United Kingdom and on the Continent. We may name, as a few of these, a New Brunswick Exhibition in 1853; a Madras Exhibition of native industry in the same year; an Exhibition of German Industry at Munich in 1854; and an Art Exhibition at Edinburgh in 1857. From among these, it must suffice to give a few figures concerning the Munich Exhibition. An iron and glass building was constructed at a cost of 90,000*l.* It was 800 feet by 280, 87 feet high, and had 250,000 square feet of flooring. There were 6800 exhibitors, belonging to 33 Zollverein states, and the goods they sent, distributed into 12 classes (instead of 30 as in England and France), were roughly valued at 1,500,000*l.* The exhibition was open from the 15th of July to the 15th of October, at an admission fee varying from 4½*d.* to 1*s.*, English. The undertaking would probably have entailed a loss under any circumstances; but a visitation of cholera, in the last months of the autumn, so thinned the number of visitors, that the Bavarian government lost 200,000*l.* by the exhibition.

Manchester Art-Treasures Exhibition.—Although not exactly an international exhibiton, the Manchester Exhibition was so comprehensive in character, and so exceptional in its leading features, that it is fully entitled to a place here.

The Manchester Exhibition was the child of the French Exposition Universelle of 1855, as that was of the Great Exhibition of 1851: it differed from both in being an exhibition solely of artistic objects sent by their possessors, and not by producers or by dealers. The project was inaugurated at a meeting of Manchester gentlemen on the 26th day of March, 1856. The scheme was favourably received; an ample guarantee fund readily provided; the Queen and the Prince Consort gave their hearty support to the undertaking; and with few exceptions —and these in some cases forced ones, the effect of entails, &c.—the owners of works of art responded cheerfully and freely to the appeal. A building was erected at Old Trafford, about two miles from the centre of the city, and readily accessible by railway as well as omnibus, from a design by Mr. Salomons, in conjunction with Messrs. Young and Co., of Edinburgh, the contractors. The exhibition was formally opened by the Prince Consort on the 5th of May, 1857, and remained open till the 17th of October.

In its general plan the building was a parallelogram of 660 feet by 200 feet, with low projecting towers and attached corridors at the east or entrance end, and refreshment-rooms and offices built out from the sides. With the exception of the entrance front, which was of brick, the exterior of the building was constructed entirely of corrugated sheet-iron, affixed to a cast-iron framework; the interior being lined with wood. The entire structure covered an area of about 130,000 square feet, and cost somewhat over 30,000*l.* The interior consisted of a central hall and two side aisles, with transepts near the western end; at the western end a gallery extended round the transepts, and across the end of the building, and at the eastern end one was carried across the front. The central hall, which was 632 feet long and 104 feet wide, was divided into three sections by a series of slender coupled columns. The roof consisted of a semicircular span of 56 feet, springing from the columns, with hipped side spans 24 feet across. The side aisles, or picture galleries, were 432 feet long and 40 feet wide, and were spanned by a semicircular roof 50 feet high to the crown of the arch. A water-colour gallery at the western end of the building was 200 feet long by 24 feet wide.

The walls of the central hall were covered with portraits of celebrated English personages. Below these were cases filled with various articles of ornamental art, while along the body of the hall were ranges of upright cases containing larger, rarer, and more costly specimens of a similar kind. The general collection of modern sculpture was also arranged in a double series the entire length of the central hall. The Meyrick collection of armour, with choice examples from other repositories, and the entire Soulages collection of antique furniture, &c., occupied spaces near the western end of the hall. The South Aisle was devoted to Paintings by the Ancient Masters, the north to pictures by English painters. A room beyond the transept on the south side was occupied by the noble contribution of the Marquis of Hertford, and a miscellaneous collection of cabinet-paintings of the Dutch and Flemish schools. A corresponding saloon on the north side contained the Oriental Museum. Beyond these, extending across the western extremity of the building, was a long room which, with two smaller rooms, was entirely occupied by water-colour pictures. The western gallery was filled to overflowing with the collection of miniatures, drawings by ancient masters, engravings, etchings, woodcuts, lithographs, photographs, and architectural drawings. Pictures, mostly by modern masters of foreign schools, occupied the space afforded by the eastern gallery; and finally, along as much as was available of the wall of the corridor stretching towards the railway station, were hung paintings by the old masters, for which room could not be found in the south aisle.

The number of paintings of all kinds by ancient masters was 1115, by modern masters 689. Of British portraits there were 388; of miniatures and enamels there were 59 cases, but several of the cases contained numerous examples. The water-colour drawings numbered 969. Of modern sculpture there were 160 specimens, all being in marble except about a dozen which were in bronze. The original sketches and drawings by the old masters numbered 260; the engravings in line 937; in mezzotinto 161; the etchings 246; besides which there was a considerable number of woodcuts, and plain, tinted, and chromo-lithographs, and about 600 photographs. Finally, the museum of ornamental art comprised no fewer than 17,000 articles—some whose value was to be reckoned at hundreds of pounds each, others of marvellous beauty though of inferior pecuniary value, and others again whose only value lay in their rarity.

The paintings by the old masters, which formed the principal feature of the exhibition, were arranged as far as practicable in chronological order: the Italian pictures occupying the south wall, those of Germany and the Netherlands the north wall; the Spanish pictures being placed in the vestibules. For completeness and value such a collection was probably never before brought together, comprising as it did characteristic examples of almost every school, and extending over the entire range of the art from its dawn in the 13th to its decline in the 17th century. Of English paintings the collection, if less important was no less instructive. It was indeed the only attempt that had been made to exhibit a collection of English pictures which should suffice to give a tolerably complete view of the rise, progress, and present state of painting in England. And what was done in the south aisle for English oil painting was in the western rooms accomplished for English painting in water colours; the series showing in fact the whole history of the art by means of first-class examples. Of the British portrait gallery we have already spoken.

The collection of original drawings and sketches by the old masters contained 260 choice specimens by some of the chief artists of all countries; while of the collection of engravings it is enough to state, in the words of the catalogue, that "This was the first time in the history of the art of engraving at which an attempt was made to show the public generally, at one view, a complete chronological series of prints from the commencement of the art up to the present time," some of the examples being among the choicest of the most highly-prized prints of the greatest engravers of every country.

The Museum of Ornamental art—the most comprehensive and richest collection of the kind that probably was ever brought together, consisted of the costliest and most exquisite specimens of mediæval goldsmiths' work, arms, armour, and every kind of artistic metal work; majolica, Dresden, Sèvres, and other pottery; Venetian and other rare glass; ivory carvings; bronzes, and terra cotta sculpture, &c. &c., with extensive collections of Oriental ornamental produce formed by the Queen and the East India Company; and entire collections selected as characteristic of the treasures in ornamental art, of the British and South Kensington Museums; the entire Soulages collection; and the Mayer collection of British, Celtic, and Anglo-Saxon antiquities.

The Exhibition, during the five months it remained open, received above a million and a quarter visits (1,335,915)—one million (1,053,538) by payment at the doors, the rest by season-tickets. The receipts from all sources amounted to 98,500*l.*, the entire expenditure was a few thousands more, but it was pretty nearly covered by the sale of the materials of the building.

EXILE. [BANISHMENT.]

E'XODUS, THE BOOK OF, is the second of the Pentateuch, or Five Books of Moses, and derives its name from the principal event recorded in it, namely, the departure of the Israelites from the land of Egypt, which, in the Greek Septuagint translation, is expressed by the word éxodus (Ἔξοδος), that is, the going out. In the original Hebrew it is named, according to the usual Jewish mode, from the initial words, ואלה שמות *ualh shmut,* or, as read with the Masoretic points, Ve-elleh shemoth, "and these are the names." The king, Pharaoh (a general Egyptian appellation of royalty), for whom the Israelites built the treasure cities, and by whom their male children were ordered to be drowned (chap. i.), is usually considered by the commentators to be Rameses, the eldest son of Sesostris; and the Pharaoh whose army perished in the Red Sea (xiv. 27) is supposed to be his son and successor, Amenophis the Second, or according to others, the Third. The Mosaic exodus is noticed by several ancient writers, but with brevity and apparent contempt. The Egyptian historians, Manethon and Chæremon, as cited by Josephus ('Against Apion,' l. i., c. 9, 11, 12), state that 250,000 leprous people, and others afflicted with contagious diseases, were banished from Egypt ('Exod.' xii. 39), "they were thrust out of Egypt" by king Amenophis; and that their chief was a priest of Heliopolis named Moses, who furnished them with a system of religion and laws. (See a similar account in Josephus, 'Hist.,' l. v. c. 34; Tacitus, 'Hist.,' l. v. c. 3; Diodorus Sic. 'in Photii Biblioth.,' l. xxxiv.; Justin, l. xxxvi. c. 2.)

The period over which the history in the book of Exodus extends consists of 145 years, that is, from the death of Joseph (B.C. 1635) to the formation of the tabernacle in the desert of Arabia (B.C. 1490), one year after the exode in the year B.C. 1491. Mr. Horne, in his 'Introduction to the Bible,' adopts the general opinion of commentators that the book was written by Moses, yet he thinks that it cannot be determined at what time of his life; but, as it is stated (xvi. 35) that "the children of Israel did eat manna 40 years until they came unto the borders of the land of Canaan," that is, on the banks of the Jordan, opposite Jericho, when and where Moses died ('Gen.' xxxiv.), and, "as things cannot be historically related," as Mr. Horne observes, "until they have actually taken place," it is evident that, if Moses is the author, he must have written it immediately before his death (B.C. 1451). De Wette, and other writers of the rationalistic school, have earnestly endeavoured to show that Moses could not have been the author; but besides the express declaration of Moses himself, that he "wrote all the words of the Lord" ('Exod.' xxiv. 4), Hengstenberg, Havernick, and others, English as well as German, have very sufficiently controverted their objections, and there have been constantly increasing verifications among the discoveries in Egyptian antiquities. It must be observed however that, among biblical critics and chronologists, a great difference of opinion exists as to what date should be assigned to the departure of the Jews from Egypt.

EXORCISM (ἐξορκισμός), the form of adjuration, or charging upon oath, by which evil and malignant spirits are subjected to command, or driven away: from the Greek *exorkizen* (ἐξορκίζειν). See Joannis Wieri, 'De Præstigiis Dæmonum et incantationibus ac veneficiis Libri v.,' 8vo., Bas. 1566 and 1583; and the 'Manuale Exorcismorum,' by Maximilian ab Eynatten, 8vo., Antw., 1619.

EXOSMOSE. [ENDOSMOSE; OSMOSE.]

EXOSTOSIS (ἐξόστωσις) a swelling or tumour of a bone. This term has been applied very generally to all tumours of the bones, whether they partake of the characters of osseous structure or not. This led to the distinguishing these swellings into true and false: the former including true osseous structures; the latter the various forms of cartilaginous tumour, spina ventosa, and those diseases of the periosteum and bone called by Sir Astley Cooper periosteal and medullary exostosis. True exostosis is in fact nothing more than an hypertrophy of the tissues which constitute the bone. Hypertrophy of a bone may arise from natural causes, and is produced by anything which constantly increases the action of a part. It is thus that the same actions which increase the size of the muscles of a blacksmith's arm and a dancer's leg will also be attended with an increased development of the bony attachments of the same muscles. During rapid growth it sometimes happens that one part of a bone grows faster than another, from some increased facility of nutrition in the part, and the consequence is an exostosis. This often occurs in the clavicle of children, but requires no treatment, as subsequent growth removes the deformity.

The more frequent cause of an exostosis, which does require treatment, is the production of increased action of the part by the application of some stimulus. It is difficult frequently, in bones, to trace the increased action to the true cause. It sometimes, however, follows a blow; and some persons are so predisposed to take on this form of action, that slight injuries are followed by exostoses. The structure and density of exostoses vary much. Sometimes they exhibit a light cellular structure, like the cancellated structure of bones, and are frequently much lighter and more cancellar than is ever observed in this structure in its normal development. At other times the structure of the exostosis is much harder than common bone, and possesses all the characters of ivory. The cancellated structures sometimes attain a considerable size, but the ivory exostoses seldom exceed the size of a bean. The first are most common on the long bones, as the femur, tibia, humerus; the last on the cranium, and bones of the face. Sometimes the increased action of the tissue extends to the whole bone, and every part is enlarged. Remarkable examples of such a thickening of the whole of the cranium occur in the museums of the Royal College of Surgeons and University College.

Exostoses are easily distinguished from other swellings by their being fixed and immoveable, and at first unattended with any pain or inconvenience. They are also distinguished by the slowness of their growth. Where exostoses are situated on parts of the skeleton in which they do not interfere with other organs, they may be left to themselves. Situated behind the knee-joint, they have been known to interfere with the action of the flexor muscles. The growth of an exostosis from the os-pubis has, by its pressure, rendered the urethra impervious. An exostosis of the femur has been known to obliterate the femoral artery; in the orbit, to produce displacement of the eye. Cases are recorded in which an exostosis of the cervical vertebræ has obliterated the subclavian artery, and, extending backwards from the lower jaw, has produced a fatal impediment to respiration by its pressing on the larynx. No kind of external treatment is beneficial in any of the forms of exostosis; and when, on account of their position, it is thought right to treat them, they must be removed. The operation consists in sawing or cutting away the bony tumor, which may be done by a trephine, Hey's saw, or Liston's cutting pliers. Of course this operation should only be performed when it can be done without danger to neighbouring organs. Even when the whole of the projection cannot be removed, it will often be found of advantage to take away a part.

(Cooper, S., *First Lines of Surgery;* Cooper, S., *Dictionary of Surgery;* Mayo, *Outlines of Human Pathology;* Liston, *Elements of Surgery.*)

EXOTERIC and ESOTERIC (ἐξωτερικός and ἐσωτερικός), literally "external" and "internal," were two terms used in reference to the writings and doctrines of many of the ancient Greek philosophers. The general distinction between the classes of works called by these respective names is this: the "exoteric" were those writings which were in a more popular form; the "esoteric," those which were written in a scientific and more exact form. The "esoteric" would of course contain a true investigation of principles as then understood; the "exoteric" would exhibit philosophical systems in such a form as the mass were able and willing to receive. The "exoteric" writings consequently accommodated themselves to popular prejudices and superstitions, this being the only safe way in which a certain amount of philosophical truth could be conveyed to the vulgar. The "esoteric" writings and doctrines were reserved for those who were far enough advanced to understand them, and to form a just notion as to the prevalent false opinions of the mass of the people. It is important to bear in mind this distinction between "exoteric" and "esoteric" doctrines in forming our judgment of the character and writings of the ancient philosophers. [ARISTOTLE, in BIOG. DIV.]

EXPANSION. [HEAT.]

EXPECTATION OF LIFE, a term applied to the mean or average duration of the life of individuals of any given age. [LIFE, MEAN DURATION OF.]

EXPECTORANTS (from *ex,* out of, and *pectus,* the chest) are medicinal agents, which, in certain conditions of the system, will, either by promoting or repressing the secretion of the air-passages and of the lungs, facilitate its expulsion. The articles which bear this name differ considerably as to the means by which this end is accomplished. They are chiefly derived from the vegetable kingdom, some being gum-resins, or balsams, of a stimulating quality, while others are possessed of nauseating or sedative properties; vapours also are expectorants, and may be either simple, as that of warm water, or medicated with different impregnations. Vapours alone reach the organs to be affected, and are therefore the only *direct* expectorants; the others being taken into the stomach must operate by sympathy or some other obscure agency.

From the differences in the nature of the substances regarded as expectorants it is clear that they must operate in a very different manner, according to the state of the system, the pathological condition of the lungs, and the stage of the complaint. Great care is necessary in selecting the particular agent suited to each case, and in no set of diseases are greater errors committed by unprofessional persons by an injudicious employment of these agents, than in those of the lungs, from common colds to the more serious and fatal affections of these vital organs. The slight nature of many of the common maladies of the throat and lungs, and the fatality of consumption, which is generally though most erroneously regarded as an affection of the lungs themselves, while it is truly an affection of the whole constitution, have led to a degree of interference with the treatment of diseases of these organs not attempted in any other cases, as the multitude of popular remedies for *coughs*, *colds*, and *consumptions* attest.

A certain exhalation from the internal surface of the lungs and air-passages constantly goes on in a state of health—any considerable diminution or augmentation of this secretion may require the assistance of medicines to raise it to the proper quantity in the one instance, or to evacuate the superfluity and repress the tendency to its excessive formation in the other. The chief causes which lead to diminished secretion are inflammation and spasm—hence at the commencement of inflammatory affections of the air-passages and of the lungs the inner membrane is dry, and by the stethoscope what is called the crepitating *râle* is heard; in asthma and hooping-cough, while the spasm lasts, there is an absence of secretion, which becomes abundant when the spasm yields.

To obviate these states very different means must be employed from what are necessary in the later stages of an inflammatory affection, or where there was extreme relaxation of the vessels of the lungs, and the exhaled fluid redundant in quantity. One of the terminations of inflammation being by effusion, when the increased action of the vessels has lasted for some time a state of the lungs occurs which is precisely the reverse of what it was before, and an extreme quantity of mucus obstructs the access of air to the blood circulating through the cells of the lungs: if this continue to accumulate, suffocation must follow. Too great an accumulation sometimes takes place, especially in elderly people, not from excessive secretion but from deficient absorption.

These are a few of the different states for which expectorants are used, but much circumspection is required to accommodate the means to the end. Where there is decided inflammation the best expectorants are those which lessen the inflammatory state, such as venesection and nauseating doses of tartrate of antimony or of ipecacuanha, and the inhalation of the vapour of warm water, simple or medicated, by means of Mudge's inhaler. But as the use of any such instrument requires considerable exertion of the respiratory organs, where the inflammation is violent it is inadmissible, as the lungs must be kept in as tranquil a state as possible; but the head may be held over a basin of warm water, the vapour of which will be received by the lungs in the ordinary course of respiration.

When the inflammation has subsided, the more stimulating expectorants may be used. Where there is first spasm hindering secretion, and ultimately an excessive exhalation which must be cleared away, a combination of a sedative or antispasmodic medicine with the expectorant is best.

These are the principles which should regulate our choice in the more acute affections of the chest; but as no set of organs are so subject to chronic disorders as the lungs and their appendages, we frequently have recourse to expectorants to alleviate many of the symptoms attendant on them.

Lessening the tendency of blood towards the lungs, and directing it more towards the skin, is of service both in acute and chronic affections of the chest. Hence bathing the feet in water on the first feeling of an attack of cold, followed by antimonials or other diaphoretics, is of much utility, if the patient go into a warm bed immediately; while on the same principle, the use of flannel next the skin is the best preventive, and is indispensable for all delicate persons, particularly if predisposed to diseases of the lungs.

EXPLOSION is the sudden displacement of a considerable volume of air, or of any gaseous particles, accompanied by a loud report.

In the well-known experiment with a glass cylinder having one end covered with a thin bladder tightly bound about it, the column of air incumbent on the bladder suddenly descends into the vessel on the rupture of the bladder when the air beneath is withdrawn by means of an air-pump; and the collision of its particles with one another or with the sides of the vessel produces the vibrations which cause the perception of sound. The particles of steam, in a state of high elasticity, when suddenly liberated by the bursting of the vessel in which they are contained, produce also a loud report by their collision with the atmospherical particles about them, or by the rush of air into the rarefied space which they have quitted. The elastic gases liberated on the application of fire to gunpowder in a tube, and the heat produced at the same time, create a rapid displacement of the particles of the surrounding atmosphere; and these as rapidly falling back into the vacuum within and about the fire-arm, cause a loud report by their collisions. A fulminating powder is the cause of a like explosion being produced, by means of the gases which are set free in consequence merely of the friction of the particles.

The explosions which, in the atmosphere, accompany a flash of lightning, are also ascribed to a similar displacement and subsequent rush of air into the vacuum produced.

For the explosion produced by chemical combinations, see DETONATION.

EXPONENT; EXPONENTS, NOTATION OF. In the algebraical expression a^x, x is called the exponent of a. If we were strictly to preserve the most ancient meaning of the term, x would be called the exponent of the whole symbol a^x: but it is usual to call x the exponent of a, and the logarithm of a^x.

From the time of Descartes it has been usual to employ exponents in abbreviation of repeated symbols of multiplication: but this was only the beginning of a series of extensions which have made the theory of exponents a fundamental part of analysis. Beginning with the simple substitution of a^2 instead of $a \times a$, a^3 instead of $a \times a \times a$, and so on, we have a succession of new symbols suggested by the processes of algebra, namely, that a^1 should stand for a, a^0 for unity, a^{-x} for the reciprocal of a^x, and $a^{\frac{m}{n}}$ for the nth root of the mth power of a. These conventions being made, the common algebraical theory of exponents is complete; and the student will find in works on algebra an account of the manner in which the necessity for these extensions appears. The theory of logarithms flows naturally from this notation and the binomial theorem.

Looking at the notation of exponents in another point of view, we see that a^1, or a, signifying the performance of a certain operation on the unit, a^2, or aa, signifies the repetition of the same operation upon a itself; a^3 denotes the repetition of the same operation upon a^2, and so on. Hence by analogy, whenever, in the higher parts of analysis, ϕx signifies an operation performed upon x, $\phi^2 x$ signifies the repetition of the operation upon ϕx. Thus if ϕx signify $1 + 2x$, then

$$\phi^2 x \quad \text{is} \quad 1+2\ (1+2x) \quad \text{or} \quad 3+4x.$$
$$\phi^3 x \quad \text{is} \quad 1+2\ (3+4x) \quad \text{or} \quad 7+8x, \text{ \&c.}$$

It appears by reasoning analogous to that which establishes the meaning of exponents in algebra, that $\phi^0 x$ must stand for x itself. Also $\phi^{-1}x$ must signify the operation inverse to (or which destroys the effect of) ϕx; thus if ϕx signify x^2, $\phi^{-1}x$ must be $\sqrt{x}$. Also $\phi^{\frac{m}{n}} x$ means that operation which performed n times in succession, gives the same result as ϕx performed m times.

The Differential Calculus and the Calculus of Differences furnish striking examples of the notation of exponents. As soon as the student arrives at the higher parts of these subjects, he should pay particular attention to the structure of the notation, and in particular to the meaning of those theorems in which the symbols of operation are separated from those of quantity.

EXPORTS. [IMPORTS and EXPORTS.]

EXTENT (Lat. *extenta*) is a writ of execution (sometimes called an *extendi facias*), which is directed to the sheriff against the body, lands, and goods, or the lands only, of a debtor; and it is also used as signifying the act of the sheriff or officer upon the writ itself.

The king by ancient prerogative is entitled to this writ, either in chief or in aid, for the purpose of obtaining satisfaction of debts originally due to him or assigned to the crown. *The writ of extent in chief* is an adverse proceeding by the king for the recovery of his own debt, and in which he is the real plaintiff. The writ is issued out of the Court of Exchequer; and the sheriff, for the purpose of executing it, may break open the defendant's doors, when purposely closed, either to arrest him or to take his goods. If, however, the defendant cannot be found, or is not meant to be arrested, the sheriff impanels a jury to inquire as to the debtor's lands and tenements, goods, and chattels; and after the inquisition is made, the lands then become bound to the crown until the debt is satisfied. *The writ of extent in aid* is also sued out at the instance and for the benefit of the crown against the debtor of a crown debtor: in this proceeding the king is the nominal plaintiff only. The writ is in effect an extent in the second degree, and in order to obtain it an extent *pro formâ* is sued out against the debtor to the crown, upon which an inquisition is taken; and if it be thereupon found that another person is indebted to him, the Court of Exchequer, on an affidavit to that effect, and also to the effect that the crown debt is in danger, will grant a fiat or warrant for an immediate extent in aid. Under this writ, the body of the defendant may in strictness be taken in execution as well as his lands, tenements, goods and chattels, &c.; but where there are effects sufficient to satisfy the debt, the court seems generally disposed to give the defendant his discharge.

On the return of the writ of extent in chief or in aid to the court whence they are issued, an order is endorsed on the back of it, "that if no one shall appear and claim the property of the goods, &c., mentioned in the inquisition, on or before that day se'nnight, a writ of venditioni exponas shall issue to sell the same." If the produce of the goods sold be not sufficient to pay the debt, the court will make an order for the sale of the debtor's lands under the 25th George III., c. 35.

There are various means of resisting the execution of the above writs, on the ground of informality or want of title in the crown; which may be referred to in the second volume of Mr. Tidd's work on the practice of the superior courts.

Upon the subject of extents for the subject see ELEGIT.

When lands are delivered over to a creditor upon an extent, a reasonable but not the real value is set upon them; and the effect is the same as if the creditor took a lease of the lands until his debt is satisfied.

(Coke *on Littleton*; Tidd's *Practice*; Blackstone's *Commentaries*, Kerr's edition.)

EXTORTION. "Extortion," says Coke (Co. Litt., 368, b.), "is a great misprision, by wresting or unlawfully taking by any officer, by colour of his office, any money or valuable thing of or from any man, either that is not due, or more than is due, or before it is due." It is an offence at common law, punishable by fine and imprisonment at the discretion of the court. Also, money which has been obtained by extortion may be recovered in an action at law. There are various statutes providing penalties for extortion by sheriffs, under-sheriffs, bailiffs, gaolers, clerks of assize, &c.

EXTRACTION OF ROOTS. [INVOLUTION and EVOLUTION.]

EXTRACTIVE MATTER. At a period when chemical analysis was less perfect than at present, the term extractive matter was applied to a heterogeneous mixture of matters obtained by treating vegetable substances with water, and then evaporating the solutions to dryness. Improvements in analysis have enabled the chemist to resolve such extractive matter into its constituents, and the term has now become nearly obsolete.

EXTRACTS are medicinal preparations of vegetable principles, obtained in various ways. Sometimes they are merely the juices expressed from the fresh plants, brought by careful evaporation to the consistence of honey, and then more properly denominated *inspissated juices*; at other times they consist of certain principles of the fresh or dried plant extracted by some menstruum in which they are soluble, such as water, proof spirit, vinegar, or ether, and afterwards evaporated, as in the former case. According to the nature of the menstruum employed the extract is called *watery*, *alcoholic*, *acetous*, or *ethereal*. The objects proposed in such proceedings are, to ensure the preservation of the active principles of the plant by removing the fluid in which they are dissolved, or the materials with which they are associated, that have a greater tendency to fermentation or putrefaction; to bring the valuable portion into the smallest possible compass; and to facilitate the administration of them by thus rendering them capable of being made into pills, &c.

The preparation of extracts requires the greatest care. The plants must be in every respect of the best quality, as regards the place of their growth, season when collected, &c., and the evaporation must be conducted rapidly, yet at a low temperature. Orfila found that the excellence of preparations of this kind was always in the reverse ratio of the temperature employed to form them. Mr. Barry effected a great improvement in the mode of preparing extracts by evaporating *in vacuo*. During the preparation, and especially towards the end of the operation, frequent stirring the contents of the evaporating-pan is necessary to prevent burning or decomposition of any portion of the mass. Extracts may also be formed from dried plants, barks, roots, &c., by reducing them to fine powder and macerating it for 24 or 48 hours in sixteen times its weight of water. In general cold water is now employed, but in some cases it is proper to employ warm. The extract of cinchona, prepared with cold water, is less powerful than that prepared with warm.

Extracts are simple or compound, according as they are prepared from one plant or from several different kinds.

This mode of preparing vegetable principles is generally unsuitable where a volatile oil is the active agent, unless great care and a very low temperature be used.

A well-prepared extract should possess in a great degree the odour, and especially the taste, of the plant from which it is obtained; it should not have either an empyreumatic smell or taste, and it should have a proper and uniform consistence. It is necessary to preserve extracts in a dry situation: to assist in keeping watery extracts, it is customary to sprinkle a little alcohol over the surface before covering them up; but watery extracts, if made with cold water and due care, rarely require this precaution. It is proper to examine the condition of all extracts very frequently, both during very warm and very wet weather: any portion which seems spoiled should be immediately thrown out.

Formerly, from the careless or unskilful mode of their preparation, extracts were the most uncertain and useless form of vegetable remedies; but since competent practical and scientific chemists have given their attention to the subject, they are now, in many instances, the most valuable contributions which chemistry has made to practical medicine.

The term is also absurdly applied to a solution of diacetate of lead, called, after its discoverer, *Goulard's Extract*, or *Extract of Saturn*. This is only used externally.

EXTRAORDINARY RAY. When a pencil of light falls upon a doubly refracting crystal, such as one of Iceland spar, it is separated into two rays, one of which is refracted according to the ordinary law, and is termed the *ordinary ray*; the other, according to a new or extraordinary law, and is called the *extraordinary ray*. [POLARISATION OF LIGHT.]

EXTRAORDINARY REFRACTION. [MIRAGE.]

EXTRAVASATION (*extra*, without, *vas*, a vessel), in medicine, signifies the escape of any of the fluids from its natural reservoir or canal into some neighbouring cavity or texture. The term is nearly synonymous with effusion, but less comprehensive, as it does not include the case of fluids poured out by secretion, such as dropsies, or any of the products of inflammation. It is most commonly employed in designating effusions of blood or of urine; and we shall therefore confine what we have to say on the subject to a brief notice of the principal varieties of these accidents, referring the reader for more complete information to other parts of the work.

Extravasations of blood are always serious, and often fatal, when the larger vessels and more important organs are concerned in them. Thus if blood escape in consequence of the rupture of an aneurism of the aorta into the bag which encloses the heart, the circulation is immediately arrested, and sudden death ensues. Such an accident is said to be "an extravasation of blood into or within the pericardium." [ANEURISM.]

Blood is sometimes driven with great force from a ruptured or wounded artery into the loose spongy substance consisting of connected cells which surrounds and separates the various organs, and is found in great abundance in every part of the body. This is called "extravasation of blood into the cellular tissue" of the part. In such cases, if the vessel be a large one, the extravasation may be so considerable as to occasion enormous swelling and distension of the contiguous parts; and it may be fatal from the amount of the hæmorrhage, or from pressure upon some vital organ, or from mortification. [HÆMORRHAGE.] This is a frequent source of danger in gunshot wounds. Fractures also are generally followed by considerable effusions of the same kind, which however are soon absorbed, and are not often attended with serious consequences, except in fractures of the skull; in that case they compress the brain, and produce the symptoms of apoplexy. [HEAD, INJURIES OF THE.] The *thrombus*, or swelling beneath the skin, so frequently observed after bleeding from the arm, is also formed by extravasation of blood into the cellular tissue. It arises from the puncture in the skin not corresponding with the opening in the vein, or not being sufficiently large. It soon disperses, and is of little importance. [BLEEDING.] Contusions are likewise followed by extravasation of blood into the cellular tissue under the skin, and in the skin itself, from the rupture of small vessels; and this is the reason of the dark colour assumed by the bruised parts, which often extends to a considerable distance from them, as in the familiar instance of a black eye. This superficial extravasation is generally called *ecchymosis*, a word of the same import.

Spontaneous extravasations of blood, allied to those last mentioned, frequently take place in the progress of various diseases, of which they may be causes or symptoms. The spots which appear under the skin and beneath the membranes which line the internal cavities and tubes, in plague, typhus fever, sea scurvy, and other complaints, are of the symptomatic kind; and these, as well as the discolorations after contusions, are included in the general term *ecchymosis*; they are also known by various other names, as *vibices* (wheals), *petechiæ*, and *purpura*. They are frequently attended with bleeding from the mucous membranes of the intestines and bladder, and of the nose; and they often occur, in the lower extremities especially, when the liver is enlarged, or otherwise diseased. They are supposed in general to indicate a want of tone in the system, and are attributed by some to a *dissolved* and semiputrescent condition of the blood; but they arise in some instances from a plethoric habit, and require bleeding for their cure.

One of the most common causes of apoplexy is an extravasation of blood in the substance of the brain, or between its membranes, from the simultaneous rupture of many minute arteries. It happens for the most part suddenly, when the vessels of the head are preternaturally distended, but yet not without some premonitory signs; and as the affection occurs most frequently at an advanced period of life, when the arterial system in general is disposed to disease, it is probable that the rupture is often preceded by some morbid change which renders the capillary vessels more than usually fragile. [APOPLEXY.] The term *apoplexy* has been extended by modern pathologists to similar extravasations occurring in the texture of other organs besides the brain; it may take place in the liver when the venous system of the abdomen is loaded with blood, and from other causes; and it frequently happens in the lungs when their circulation is either obstructed or too forcibly urged in various diseases of the heart. [HEART, DISEASES OF THE.] It likewise happens very commonly in the early stage of consumption, when the body is yet full of blood, and the substance of the lungs is rendered brittle and inelastic by the deposit of tuberculous matter. [PHTHISIS.] When it occurs in the lungs, the injury is attended with *hæmoptysis*, or spitting of blood. In this, as in many extravasations of the same kind, it is probable that the blood is effused rather in consequence of a *rent*, or breach of continuity in the structure concerned, than from what is implied in the common notion of the breaking of a blood-vessel. But in the early stage of consumption, the blood almost always escapes by *exhalation* from the extremities of the relaxed and distended vessels. See Louis 'On Phthisis Pulmonalis.'

The presence of extravasated blood does not in itself produce much irritation, and the coagulum is soon absorbed when the quantity is not very great, and the vital powers are not depressed by concomitant causes. Where pressure is applicable, the absorption is much quickened by a bandage put on after the immediate effects of the injury have subsided, as in sprains and bruises of the limbs; friction and embrocations have the same effect. See 'An Essay on the Metamorphosis of the Coloured Blood Corpuscles in Extravasated Blood,' by John Burdon Sanderson, M.D., Edinb., 1851.

Extravasations of urine may take place in consequence of rupture of the bladder or urinary passages from ulceration, mechanical injuries, or any cause that produces distension to a great degree. If the fluid escape into the cavity of the abdomen, the result is uniformly and speedily fatal. If it insinuates itself into the cellular tissue in the neighbourhood of the neck of the bladder or the urethra, the accident is still a very serious one, though it generally admits of cure if the nature of it be immediately recognised. The fluid, which is highly deleterious, must be promptly evacuated by free incisions, and care must be taken to prevent further infiltration. If this be neglected, unhealthy suppuration is sure to take place, accompanied by fever of a typhoid character, and followed by extensive mortification.

The most common causes of infiltration of urine are abscesses of the prostate gland, and neglected or mismanaged strictures; and a very frequent consequence is the establishment of a urinary fistula in the perineum. [Urinary Organs.]

It may be remarked that the bile is sometimes extravasated in the same way from the gall-ducts or bladder. If it escape into the abdomen, it is followed by a similar fatal result from inflammation of the *peritoneum*. [Calculi, Biliary.]

EXTREME AND MEAN RATIO. To cut a line according to extreme and mean ratio, *εὐθεῖαν ἄκρον καὶ μέσον λόγον τεμεῖν*, is a phrase of Euclid which it is not very easy to explain from the words of it. The meaning is, to cut a straight line in such a manner that the whole shall bear to the greater part the same ratio as the greater part to the less; or to make the greater segment a mean proportional between the whole and the less. Accordingly, the square of the greater segment must be equal to the rectangle under the whole and the less segment; and Euclid shows how to make this section in the 11th proposition of the second book.

If the whole line be called unity, and if x be the fraction which is in the greater segment, we must have

$$1-x=x^2,\text{ or }x=\pm\tfrac{1}{2}\sqrt{5}-\tfrac{1}{2}.$$

In the sense of Euclid, only the value $\frac{1}{2}\sqrt{5}-\frac{1}{2}$ will solve the problem; and the other root, with the sign changed, solves the following problem: To produce a line in such manner that the part produced may be a mean proportional between the given line itself and the line made up of the given line and the part produced. Any one who examines Euclid's construction will very easily see the formation of $\frac{1}{2}$, of $\frac{1}{2}\sqrt{5}$, and the subtraction of the first from the second.

The fraction x cannot be expressed arithmetically, and the segments are incommensurable. But if a and b be any two numbers, of which a is the less, and if we form a third by adding the two, a fourth by adding the second and third, and so on, as in the series a, b, $a+b$, $a+2b$, $2a+3b$, $3a+5b$, $5a+8b$, &c., it is demonstrable that the farther we go the more nearly does the ratio of any one to the next represent that of the less to the greater segment of a line divided in extreme and mean ratio. If we begin with 1 and 1, we have the series 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, &c. &c. Thus, if 89 inches be divided into 34 and 55 inches, the division required is nearly made, for the rectangle has 89×34, or 3026 square inches, and the square has 55×55, or 3025 square inches. This process gives us the results of turning

$$1-x=x^2,\text{ or }x=\frac{1}{1+x}$$

into $x=\frac{1}{1+}\,\frac{1}{1+}\,\frac{1}{1+}$, &c. [Fractions, Continued], and then making successive approximations. It is, perhaps, just worth noting, that the nth number in the series 1, 1, 2, 3, 5, 8, &c., is the number of ways in which n can be made up out of odd numbers, differences of order counting as different ways: thus, 6 can be made up in 8 ways out of odd numbers. Accordingly, the greater n is taken, the more nearly are the numbers of ways in which n and $n+1$ can be composed of odd numbers in the proportion of the segments of a line divided in extreme and mean ratio.

The use of this division in elementary geometry is as a step to dividing four right angles into five equal parts, as in the 10th proposition of the fourth book. In fact, the half of $\frac{1}{2}\sqrt{5}-\frac{1}{2}$ is the sine of 18°, the fifth part of a right angle.

EYE, IN OPTICS. [Optics.]

EYE-PIECE, a combination of lenses for the purpose of examining the *image* of an object formed by the object-glass, or by an achromatic combination of lenses in the tube of a telescope or of a compound microscope. Eye-pieces are usually of two kinds,—the *Huygenian* or *negative*, and *Ramsden's* or *positive*; but the former is most commonly used. It consists of two plano-convex lenses, with their convex surfaces towards the object-glass. The one nearest the eye is known as the *eye-glass*, while the other is called the *field-glass*, its function being to increase the field of view. Between the two lenses is a perforated *stop* or *diaphragm*, for the purpose of cutting off the extreme rays that might disturb the perfection of the image.

Ramsden's eye-piece also consists of two plano-convex lenses; but the field-glass has its convex surface turned upwards instead of downwards. The positive eye-piece is chiefly used with the micrometer. [Microscope; Telescope; Doublets; Micrometer, &c.]

EYES, PROPAGATION BY. The power of propagating plants by any other means than seeds depends entirely on the presence of leaf-buds or "*eyes*," as they are technically called by gardeners. A plant may in fact be regarded as a congeries of individuals, and each leaf-bud is an individual capable of maintaining an independent existence. Though this is generally true, the buds of all plants will not grow when removed from their parent stock. Many, however, admit of their buds being removed from one branch and placed upon another, which constitutes the process of budding. [Budding.] Others admit of a branch being removed and placed in the ground, when the leaf-buds upon it will develop, and the wood of the branch form roots. Such branches are called cuttings. [Cutting.] A few plants admit of single buds being taken and planted in the earth, when they will grow and produce plants in the same manner as seeds. It must, however, be borne in mind in this case that the individual and not the species, as is the case with seeds, is propagated. The plants which are most frequently propagated by eyes are the potato and the vine. It appears that for plants to grow in this manner, the bud requires that a due supply of nutriment should be stored up in the branch or part of the stem to which it is attached. This is undoubtedly the case in the potato, where a large quantity of amylaceous matter is stored up in the tubers, so that a bud cannot be taken without carrying away fragments of its alimentary secretions. Mr. Knight observed, with regard to the buds of the vine, that those grew with most rapidity and strength which were in contact with the largest quantity of alburnum, which he regards as the nutritious matter of the young buds. The provision, however, of alimentary matter may be in some cases, as has been pointed out by Dr. Lindley, disadvantageous by promoting too great a development of stems and leaves. According to theory, the more nutritive matter there is for the eyes, the greater crop there will be; and thus it would seem that it would be more advantageous to plant whole potatoes than portions of the potato or sets. Dr. Lindley proved by a series of numerous experiments, that the weight of potatoes per acre is greater under equal circumstances, from sets than from the whole tubers by upwards of from seven cwt. to three tons per acre, and considerably more on comparison of the clear produce after deducting the weight of sets employed in both cases. He supposes "the rankness of the vegetation from the whole tubers to be the cause of the diminished crop; for the stems were unable to support themselves, and were blown about, laid, and broken by the wind." A curious fact with regard to the growth of the eyes on different parts of the potato has been pointed out in the 'Gardener's Magazine.' It is well known to the cultivators of potatoes in Lancashire that different eyes germinate and yield their produce at very different times, some being ripe or fit for use as early as the middle of May, and others not till June or July. It is found that it is the sets which are nearest the extremity of the potato which ripen soonest; and these are planted in Lancashire in warm places, in March or the beginning of April, and are ready for the market by the middle of May. The produce of the next sets are ready a fortnight after, and that from the root end still later.

In propagating the vine by this means an eye is taken with a small portion of the stem adhering to it, and is placed in earth with a bottom heat of 75° or 80°. It should be kept in a damp atmosphere, when it speedily shoots upwards into a branch, and at the same time establishes itself in the soil by the development of roots. In order to ensure the success of this operation, it is necessary that the bud should be dormant at the time it is removed, and that a small piece of well-ripened wood should be separated with it.

There is another mode of propagating plants resembling this, and that is by planting the abortive branches, called 'Knaurs,' and embryo buds. This plan is pursued in Italy for the propagation of olive trees. These knobs or abortive branches are produced by other trees besides the olive, and might be made use of for the same purpose. The beech, the poplar, the cedar, and many other trees produce these knobs in abundance in this country.

EYRE (from the old French *eyre*, a journey), the court of the justices itinerant who were regularly established, if not first appointed by the parliament of Northampton, A.D. 1176—22 Hen. II.—with a delegated power from the king's great court, or Aula Regis. They were first appointed to make their circuit round the kingdom once in seven years, but by Magna Charta, c. 12, it was provided that they should be sent into every county once a year. (4 Inst. 184.) These itinerant judges have been long superseded by the modern justices of assize. There was also a court so called which was held before the chief justices of the several forests, under the old Forest Laws. [Forest Laws.]

END OF VOLUME III.

BRADBURY AND EVANS, PRINTERS, WHITEFRIARS.
